# Scale-free networks

Networks with power-law degree distributions have become known as scale-free networks.

Scale-free refers specifically to the degree distribution having a power-law decay in its tail:

 $P_k \sim k^{-\gamma}$  for 'large' k

#### One of the seminal works in complex networks:

"Emergence of scaling in random networks" Barabási and Albert, Science, **286**, 509–511, 1999.<sup>[2]</sup>

Times cited:  $\sim 23,532$  C (as of October 8, 2015) Somewhat misleading nomenclature... PoCS @pocsvox

# BA model

 Barabási-Albert model = BA model.
Key ingredients: Growth and Preferential Attachment (PA).
Step 1: start with m<sub>0</sub> disconnected nodes.
Step 2:

- 1. Growth—a new node appears at each time step t = 0, 1, 2, ...
- 2. Each new node makes *m* links to nodes already present.
- 3. Preferential attachment—Probability of connecting to *i*th node is  $\propto k_i$ .
- ln essence, we have a rich-gets-richer scheme.
- 🚳 Yes, we've seen this all before in Simon's model.

# **BA** model

Solution:  $A_k$  is the attachment kernel for a node with degree k.

🚳 For the original model:

$$A_k = k$$

Solution:  $P_{\text{attach}}(k,t)$  is the attachment probability.

For the original model:

$$P_{\text{attach}}(\text{node } i, t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{\text{max}}(t)} k N_k(t)}$$

where  $N(t) = m_0 + t$  is # nodes at time t and  $N_k(t)$  is # degree k nodes at time t. PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details

Analysis A more plausible mechanism Robustness Krapivsky & Redner's model Generalized model Analysis Universality? Subling attachment kernels Superlinear attachment kernels Nutshell

References

()) |**8**|

#### Approximate analysis

When (N + 1)th node is added, the expected increase in the degree of node *i* is

$$E(k_{i,N+1}-k_{i,N})\simeq m\frac{k_{i,N}}{\sum_{j=1}^{N(t)}k_{j}(t)}.$$

Assumes probability of being connected to is small.

Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.

Approximate  $k_{i,N+1} - k_{i,N}$  with  $\frac{d}{dt}k_{i,t}$ :

$$\frac{\mathsf{d}}{\mathsf{d} t} k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where 
$$t = N(t) - m_0$$
.

PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details

Analysis A more plausible mechanism Robustness Krapicsky & Redner's model Generalized model Universality? Sublinear attachment kernels Superlinear attachment kernels Nutshell

References

 $\clubsuit$  Deal with denominator: each added node brings mnew edges.

$$\div \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

The node degree equation now simplifies:

$$\frac{\mathrm{d}}{\mathrm{d}t}k_{i,t} = m\frac{k_i(t)}{\sum_{j=1}^{N(t)}k_j(t)} = m\frac{k_i(t)}{2mt} = \frac{1}{2t}k_i(t)$$

#### Rearrange and solve:

$$\frac{\mathsf{d}k_i(t)}{k_i(t)} = \frac{\mathsf{d}t}{2t} \Rightarrow \boxed{\frac{k_i(t) = c_i t^{1/2}}{k_i(t)}}$$

#### PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details

Analysis mechanism Krapivsky & Redner's Analysis Nutshell

000

000 17 of E7

#### 🚳 Know *i*th node appears at time

 $t_{i,\text{start}} = \left\{ \begin{array}{ll} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{array} \right.$ 

 $\Im$  So for  $i > m_0$  (exclude initial nodes), we must have

$$k_i(t) = m \left( \frac{t}{t_{i, \text{start}}} \right)^{1/2} \text{ for } t \geq t_{i, \text{start}}.$$

All node degrees grow as t<sup>1/2</sup> but later nodes have larger t<sub>i,start</sub> which flattens out growth curve.
First-mover advantage: Early nodes do best.
Clearly, a Ponzi scheme C.

PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details

Analysis A more plausible mechanism Robustness Krapivsky & Redner's model Generalized model Analysis Universality? Sublinear attachment kernels Superlinear attachment kernels

References

#### We are already at the Zipf distribution:

Degree of node *i* is the size of the *i*th ranked node: 3

$$k_i(t) = m \left( \frac{t}{t_{i\,\text{, start}}} \right)^{1/2} \; \text{for} \; t \geq t_{i\,\text{, start}}.$$

🙈 From before:

$$t_{i,\text{start}} = \left\{ \begin{array}{ll} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{array} \right.$$

so  $t_{i,\text{start}} \sim i$  which is the rank. 🙈 We then have:

$$k_i \propto i^{-1/2} = i^{-\alpha}.$$

 $\Im$  Our connection  $\alpha = 1/(\gamma - 1)$  or  $\gamma = 1 + 1/\alpha$  then gives

$$\gamma = 1 + 1/(1/2) = 3.$$

# Degree distribution

So what's the degree distribution at time *t*?
Use fact that birth time for added nodes is distributed uniformly between time 0 and t:

$$\mathbf{Pr}(t_{i,\text{start}}) \mathsf{d}t_{i,\text{start}} \simeq \frac{\mathsf{d}t_{i,\text{start}}}{t}$$

$$k_i(t) = m \left(\frac{t}{t_{i,\text{start}}}\right)^{1/2} \Rightarrow t_{i,\text{start}} = \frac{m^2 t}{k_i(t)^2}.$$

Transform variables—Jacobian:

$$\frac{\mathrm{d}t_{i,\mathrm{start}}}{\mathrm{d}k_i} = -2\frac{m^2t}{k_i(t)^3}$$

# Degree distribution

Solution We thus have a very specific prediction of  $\Pr(k) \sim k^{-\gamma}$  with  $\gamma = 3$ .

- $\clubsuit$  Typical for real networks:  $2 < \gamma < 3$ .
- Range true more generally for events with size distributions that have power-law tails.
- $\gtrsim 2 < \gamma < 3$ : finite mean and 'infinite' variance (wild)
- In practice,  $\gamma < 3$  means variance is governed by upper cutoff.
- $rightarrow \gamma > 3$ : finite mean and variance (mild)

# Preferential attachment

- Let's look at preferential attachment (PA) a little more closely.
- PA implies arriving nodes have complete knowledge of the existing network's degree distribution.
- Solution For example: If  $P_{\text{attach}}(k) \propto k$ , we need to determine the constant of proportionality.
- 🙈 We need to know what everyone's degree is...
- PA is .. an outrageous assumption of node capability.
- 🛞 But a very simple mechanism saves the day...

# Preferential attachment through randomness

- Instead of attaching preferentially, allow new nodes to attach randomly.
- Now add an extra step: new nodes then connect to some of their friends' friends.
- 🚳 Can also do this <mark>at random</mark>.
- Assuming the existing network is random, we know probability of a random friend having degree k is

$$Q_k \propto k P_k$$

So rich-gets-richer scheme can now be seen to work in a natural way. PoCS @pocsvox

- Scale-free networks are thus robust to random failures yet fragile to targeted ones.
- All very reasonable: Hubs are a big deal.
- But: next issue is whether hubs are vulnerable or not.
- Representing all webpages as the same size node is obviously a stretch (e.g., google vs. a random person's webpage)

Most connected nodes are either:

- 1. Physically larger nodes that may be harder to 'target'
- 2. or subnetworks of smaller, normal-sized nodes.
- Need to explore cost of various targeting schemes.

Sublinear attachment kernels

superinear attacrim kernels Nutshell

References

8 00 0 37 of 57

We'll follow KR's approach using rate equations C.
Here's the set up:

$$\frac{\mathsf{d}N_k}{\mathsf{d}t} = \frac{1}{A}\left[A_{k-1}N_{k-1} - A_kN_k\right] + \delta_{k1}$$

where  $N_k$  is the number of nodes of degree k.

- 1. One node with one link is added per unit time.
- 2. The first term corresponds to degree k 1 nodes becoming degree k nodes.
- 3. The second term corresponds to degree k nodes becoming degree k 1 nodes.
- 4. *A* is the correct normalization (coming up).
- 5. Seed with some initial network (e.g., a connected pair)
- 6. Detail:  $A_0 = 0$

PoCS @pocsvox

ln general, probability of attaching to a specific node of degree k at time t is

**Pr**(attach to node *i*) =  $\frac{A_k}{A(t)}$ 

where  $A(t) = \sum_{k=1}^{\infty} A_k N_k(t)$ .  $\bigotimes$  E.g., for BA model,  $A_k = k$  and  $A = \sum_{k=1}^{\infty} k N_k(t)$ .  $\mathbf{R}$  For  $A_k = k$ , we have

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) = 2t$$

since one edge is being added per unit time. letail: we are ignoring initial seed network's edges.

PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details Krapivsky & Redner's Analysis

References

UVN S 000 40 of 57

🝰 So now

$$\frac{\mathrm{d}N_k}{\mathrm{d}t} = \frac{1}{A} \left[A_{k-1}N_{k-1} - A_kN_k\right] + \delta_{k1}$$

becomes

$$\frac{\mathsf{d}N_k}{\mathsf{d}t} = \frac{1}{2t}\left[(k-1)N_{k-1} - kN_k\right] + \delta_{k1}$$

As for BA method, look for steady-state growing solution:  $N_k = n_k t$ .

 $\bigotimes$  We replace  $dN_k/dt$  with  $dn_kt/dt = n_k$ .

We arrive at a difference equation:

$$n_{k} = \frac{1}{2!} \left[ (k-1)n_{k-1}! - kn_{k}! \right] + \delta_{k1}$$

PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details Krapivsky & Redner's Analysis Superlinear attachment Nutshell References

00 000 11 of E7

🚳 As expected, we have the same result as for the BA model:

 $N_{k}(t) = n_{k}(t)t \propto k^{-3}t$  for large k.

- lacktrian series and the start playing around lacktrian series and the start playing around lacktrian series and the start playing around lacktrian series and series are series and series are series and series are series with the attachment kernel  $A_k$ ?
- Again, we're asking if the result  $\gamma = 3$  universal  $\mathbb{Z}$ ?
- KR's natural modification:  $A_{\nu} = k^{\nu}$  with  $\nu \neq 1$ .
- 🚳 But we'll first explore a more subtle modification of  $A_k$  made by Krapivsky/Redner<sup>[4]</sup>
- $\mathbb{R}$  Keep  $A_k$  linear in k but tweak details.
- $\mathfrak{B}$  Idea: Relax from  $A_k = k$  to  $A_k \sim k$  as  $k \to \infty$ .

PoCS @pocsvox

Scale-free networks

Scale-free networks Main story Model details A more plausible Krapivsky & Redner's Universality?

Recall we used the normalization:

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) \simeq 2t \text{ for large } t.$$

#### 🚳 We now have

$$A(t) = \sum_{k'=1}^{\infty} A_{k'} N_{k'}(t)$$

where we only know the asymptotic behavior of Ak.

- A We assume that  $A = \mu t$
- $\circledast$  We'll find  $\mu$  later and make sure that our assumption is consistent.
  - As before, also assume  $N_k(t) = n_k t$ .

Rich-get-somewhat-richer:

 $A_k \sim k^{\nu}$  with  $0 < \nu < 1$ .

linding by Krapivsky and Redner: [4]

 $n_k \sim k^{-\nu} e^{-c_1 k^{1-\nu} + \text{correction terms}}$ 

🚳 Stretched exponentials (truncated power laws). 🙈 aka Weibull distributions.

locality: now details of kernel do not matter.

Distribution of degree is universal providing  $\nu < 1$ .

Sublinear attachment kernels

### Sublinear attachment kernels

#### Details:

\$ For  $1/2 < \nu < 1$ :

$$n_k \sim k^{-\nu} e^{-\mu \left(\frac{k^{1-\nu}-2^{1-\nu}}{1-\nu}\right)}$$

Solve 
$$1/3 < \nu < 1/2$$
:

$$n_k \sim k^{-\nu} e^{-\mu \frac{k^{1-\nu}}{1-\nu} + \frac{\mu^2}{2} \frac{k^{1-2\nu}}{1-2\nu}}$$

And for  $1/(r+1) < \nu < 1/r$ , we have r pieces in exponential.

# Superlinear attachment kernels

#### 🙈 Rich-get-much-richer:

 $A_k \sim k^{\nu}$  with  $\nu > 1$ .

- line states Now a winner-take-all mechanism.
- One single node ends up being connected to almost all other nodes.

So For  $\nu > 2$ , all but a finite # of nodes connect to one node.

# Nutshell:

#### Overview Key Points for Models of Networks:

- Obvious connections with the vast extant field of graph theory.
- But focus on dynamics is more of a physics/stat-mech/comp-sci flavor.
- 🚳 Two main areas of focus:
  - 1. Description: Characterizing very large networks
  - 2. Explanation: Micro story  $\Rightarrow$  Macro features
- Some essential structural aspects are understood: degree distribution, clustering, assortativity, group structure, overall structure,...
- Still much work to be done, especially with respect to dynamics... **#excitement**
