## Optimal source allocation

### Solidifying the basic problem

- Given a region with some population distribution  $\rho$ , most likely uneven.
- Given resources to build and maintain  $N$  facilities.
- Q:** How do we locate these  $N$  facilities so as to minimize the average distance between an individual's residence and the nearest facility?

- Approximately optimal location of 5000 facilities.
- Based on 2000 Census data.

- Optimal facility density  $\rho_{fac}$  vs. population density  $\rho_{pop}$ .
- Fit is  $\rho_{fac} \propto \rho_{pop}^{0.66}$  with  $r^2 = 0.94$ .
- Looking good for a 2/3 power ...

## Optimal source allocation

### Size-density law:

$$\rho_{fac} \propto \rho_{pop}^{2/3}$$

- Why?
- Again: Different story to branching networks where there was either one source or one sink.
- Now sources & sinks are distributed throughout region.

## Optimal source allocation

- We first examine Stephan's treatment (1977)<sup>[4, 5]</sup>
- Zipf-like approach: invokes principle of minimal effort.
- Also known as the Homer Simpson principle.

## Optimal source allocation

- Consider a region of area  $A$  and population  $P$  with a single functional center that everyone needs to access every day.
- Build up a general cost function based on time expended to **access and maintain center**.
- Write **average travel distance** to center as  $\bar{d}$  and assume **average speed of travel** is  $\bar{v}$ .
- Assume **isometry**: average travel distance  $\bar{d}$  will be on the length scale of the region which is  $\sim A^{1/2}$
- Average time expended per person in accessing facility is therefore

$$\bar{d}/\bar{v} = cA^{1/2}/\bar{v}$$

where  $c$  is an unimportant shape factor.

## Optimal source allocation

- Next assume facility requires regular maintenance (person-hours per day).
- Call this quantity  $\tau$ .
- If burden of maintenance is shared then average cost per person is  $\tau/P$  where  $P$  = population.
- Replace  $P$  by  $\rho_{\text{pop}}A$  where  $\rho_{\text{pop}}$  is density.
- Important assumption: uniform density.
- Total average time cost per person:

$$T = \bar{d}/\bar{v} + \tau/(\rho_{\text{pop}}A) = cA^{1/2}/\bar{v} + \tau/(\rho_{\text{pop}}A).$$

- Now Minimize with respect to  $A$  ...

## Optimal source allocation

- Differentiating ...

$$\begin{aligned} \frac{\partial T}{\partial A} &= \frac{\partial}{\partial A} (cA^{1/2}/\bar{v} + \tau/(\rho_{\text{pop}}A)) \\ &= \frac{c}{2\bar{v}A^{1/2}} - \frac{\tau}{\rho_{\text{pop}}A^2} = 0 \end{aligned}$$

- Rearrange:

$$A = \left( \frac{2\bar{v}\tau}{c\rho_{\text{pop}}} \right)^{2/3} \propto \rho_{\text{pop}}^{-2/3}$$

- # facilities per unit area  $\rho_{\text{fac}}$ :

$$\rho_{\text{fac}} \propto A^{-1} \propto \rho_{\text{pop}}^{2/3}$$

- Groovy ...

### An issue:

- Maintenance ( $\tau$ ) is assumed to be **independent** of population and area ( $P$  and  $A$ )
- Stephan's online book "[The Division of Territory in Society](#)" is [here](#).
- (It used to be [here](#).)
- The [Readme](#) is well worth reading (1995).

## Cartograms

### Diffusion-based cartograms:

- Idea of cartograms is to **distort areas** to more accurately represent some local density  $\rho_{\text{pop}}$  (e.g. population).
- Many methods put forward—typically involve some kind of physical analogy to **spreading or repulsion**.
- Algorithm due to Gastner and Newman (2004)<sup>[1]</sup> is based on **standard diffusion**:

$$\nabla^2 \rho_{\text{pop}} - \frac{\partial \rho_{\text{pop}}}{\partial t} = 0.$$

- Allow density to diffuse and trace the movement of individual elements and boundaries.
- Diffusion is constrained by boundary condition of surrounding area having density  $\rho_{\text{pop}}$ .

# Size-density law

Deriving the optimal source distribution:

- Basic idea:** Minimize the average distance from a random individual to the nearest facility. [2]
- Assume given a fixed population density  $\rho_{pop}$  defined on a spatial region  $\Omega$ .
- Formally, we want to find the locations of  $n$  sources  $\{\bar{x}_1, \dots, \bar{x}_n\}$  that minimizes the **cost function**

$$F(\{\bar{x}_1, \dots, \bar{x}_n\}) = \int_{\Omega} \rho_{pop}(\bar{x}) \min_i \|\bar{x} - \bar{x}_i\| d\bar{x}.$$

- Also known as the  $p$ -median problem.
- Not easy ...in fact this one is an NP-hard problem. [2]
- Approximate solution originally due to Gusein-Zade [3].

# Size-density law

Approximations:

- For a given set of source placements  $\{\bar{x}_1, \dots, \bar{x}_n\}$ , the region  $\Omega$  is divided up into Voronoi cells, one per source.
- Define  $A(\bar{x})$  as the **area** of the Voronoi cell containing  $\bar{x}$ .
- As per Stephan's calculation, estimate typical distance from  $\bar{x}$  to the nearest source (say  $i$ ) as

$$c_i A(\bar{x})^{1/2}$$

- where  $c_i$  is a shape factor for the  $i$ th Voronoi cell.
- Approximate  $c_i$  as a constant  $c$ .

## Size-density law

Carrying on:

- The cost function is now

$$F = c \int_{\Omega} \rho_{\text{pop}}(\vec{x}) A(\vec{x})^{1/2} d\vec{x}.$$

- We also have that the **constraint** that Voronoi cells divide up the overall area of  $\Omega$ :  $\sum_{i=1}^n A(\vec{x}_i) = A_{\Omega}$ .
- Sneakily turn this into an integral constraint:

$$\int_{\Omega} \frac{d\vec{x}}{A(\vec{x})} = n.$$

- Within each cell,  $A(\vec{x})$  is constant.
- So ...integral over each of the  $n$  cells equals 1.

31 of 46

Now a Lagrange multiplier story:

- By varying  $\{\vec{x}_1, \dots, \vec{x}_n\}$ , minimize

$$G(A) = c \int_{\Omega} \rho_{\text{pop}}(\vec{x}) A(\vec{x})^{1/2} d\vec{x} - \lambda \left( n - \int_{\Omega} [A(\vec{x})]^{-1} d\vec{x} \right)$$

- I Can Haz Calculus of Variations?
- Compute  $\delta G / \delta A$ , the functional derivative of the functional  $G(A)$ .
- This gives

$$\int_{\Omega} \left[ \frac{c}{2} \rho_{\text{pop}}(\vec{x}) A(\vec{x})^{-1/2} - \lambda [A(\vec{x})]^{-2} \right] d\vec{x} = 0.$$

- Setting the integrand to be zilch, we have:

$$\rho_{\text{pop}}(\vec{x}) = 2\lambda c^{-1} A(\vec{x})^{-3/2}.$$

32 of 46

## Size-density law

Now a Lagrange multiplier story:

- Rearranging, we have

$$A(\vec{x}) = (2\lambda c^{-1})^{2/3} \rho_{\text{pop}}^{-2/3}.$$

- Finally, we identify  $1/A(\vec{x})$  as  $\rho_{\text{fac}}(\vec{x})$ , an approximation of the local source density.
- Substituting  $\rho_{\text{fac}} = 1/A$ , we have

$$\rho_{\text{fac}}(\vec{x}) = \left( \frac{c}{2\lambda} \rho_{\text{pop}} \right)^{2/3}.$$

- Normalizing (or solving for  $\lambda$ ):

$$\rho_{\text{fac}}(\vec{x}) = n \frac{[\rho_{\text{pop}}(\vec{x})]^{2/3}}{\int_{\Omega} [\rho_{\text{pop}}(\vec{x})]^{2/3} d\vec{x}} \propto [\rho_{\text{pop}}(\vec{x})]^{2/3}.$$

33 of 46

## Global redistribution networks

One more thing:

- How do we supply these facilities?
- How do we best redistribute mail? People?
- How do we get beer to the pubs?
- Gastner and Newman model: cost is a function of basic maintenance and travel time:

$$C_{\text{maint}} + \gamma C_{\text{travel}}.$$

- Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance  $l_{ij}$  and number of legs to journey:

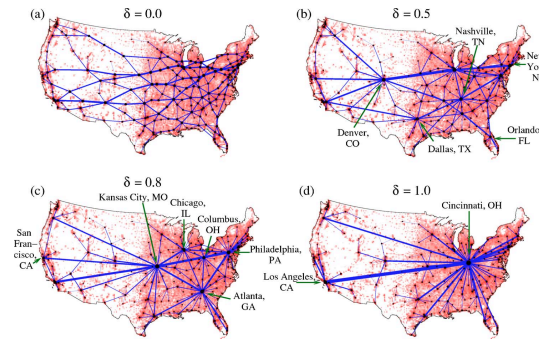

$$(1 - \delta) l_{ij} + \delta (\# \text{hops}).$$

- When  $\delta = 1$ , only number of hops matters.

37 of 46

## Public versus private facilities

Beyond minimizing distances:

- "Scaling laws between population and facility densities" by Um *et al.*, Proc. Natl. Acad. Sci., 2009. [6]
- Um *et al.* find empirically and argue theoretically that the connection between facility and population density

$$\rho_{\text{fac}} \propto \rho_{\text{pop}}^{\alpha}$$

does not universally hold with  $\alpha = 2/3$ .

- Two idealized limiting classes:

- For-profit, commercial facilities:  $\alpha = 1$ ;
- Pro-social, public facilities:  $\alpha = 2/3$ .

- Um *et al.* investigate facility locations in the United States and South Korea.

39 of 46

## Public versus private facilities: evidence

- Left plot: ambulatory hospitals in the U.S.

- Right plot: public schools in the U.S.

- Note: break in scaling for public schools. Transition from  $\alpha \approx 2/3$  to  $\alpha = 1$  around  $\rho_{\text{pop}} \approx 100$ .

40 of 46

## Public versus private facilities: evidence

A, C: ambulatory hospitals in the U.S.; B, D: public schools in the U.S.; A, B: data; C, D: Voronoi diagram from model simulation.

## Public versus private facilities: the story

So what's going on?

- Social institutions seek to minimize distance of travel.
- Commercial institutions seek to maximize the number of visitors.
- Defns: For the  $i$ th facility and its Voronoi cell  $V_i$ , define
  - $n_i$  = population of the  $i$ th cell;
  - $\langle r_i \rangle$  = the average travel distance to the  $i$ th facility.
  - $A_i$  = area of  $i$ th cell ( $s_i$  in Um *et al.* [6])
- Objective function to maximize for a facility (highly constructed):

$$v_i = n_i \langle r_i \rangle^\beta \text{ with } 0 \leq \beta \leq 1.$$

Limits:

- $\beta = 0$ : purely commercial.
- $\beta = 1$ : purely social.

## Public versus private facilities: the story

- Either proceeding as per the Gastner-Newman-Gusein-Zade calculation or, as Um *et al.* do, observing that the cost for each cell should be the same, we have:

$$\rho_{\text{fac}}(\vec{x}) = n \frac{[\rho_{\text{pop}}(\vec{x})]^{2/(\beta+2)}}{\int_{\Omega} [\rho_{\text{pop}}(\vec{x})]^{2/(\beta+2)} d\vec{x}} \propto [\rho_{\text{pop}}(\vec{x})]^{2/(\beta+2)}.$$

- For  $\beta = 0$ ,  $\alpha = 1$ : commercial scaling is linear.
- For  $\beta = 1$ ,  $\alpha = 2/3$ : social scaling is sublinear.
