## Scale-free networks

Scale-free refers specifically to the degree distribution having a power-law decay in its tail:

$$P_k \sim k^{-\gamma}$$
 for 'large'  $k$ 

One of the seminal works in complex networks:

"Emergence of scaling in random networks"

Barabási and Albert,
Science, **286**, 509–511, 1999. [?]

Times cited:  $\sim 43,853$  (as of May 19, 2023)

Somewhat misleading nomenclature ...

### Scale-free networks

Scale-free networks are not fractal in any sense.

Usually talking about networks whose links are abstract, relational, informational, ... (non-physical)

Primary example: hyperlink network of the Web

Much arguing about whether or networks are 'scale-free' or not...

The PoCSverse Scale-free networks 8 of 57

Scale-free networks

## The big deal:

We move beyond describing networks to finding mechanisms for why certain networks are the way they are.

## A big deal for scale-free networks:

 $\Longrightarrow$  How does the exponent  $\gamma$  depend on the mechanism?

Do the mechanism details matter?

The PoCSverse Scale-free networks 11 of 57

Scale-free networks

Main story

## BA model

Step 2:

Barabási-Albert model = BA model.

Key ingredients: Growth and Preferential Attachment (PA).

Step 1: start with  $m_0$  disconnected nodes.

1. Growth—a new node appears at each time step t = 0, 1, 2, ...

- 2. Each new node makes m links to nodes already present.
- 3. Preferential attachment—Probability of connecting to ith node is  $\propto k_i$ .
- In essence, we have a rich-gets-richer scheme.
- A Yes, we've seen this all before in Simon's model.

Sublinear attachment ker

Superlinear attachment kerne

## BA model

ightharpoonup Definition:  $A_k$  is the attachment kernel for a node with degree k.

For the original model:

$$A_k = k$$

 $\begin{cases} \& \end{cases}$  Definition:  $P_{
m attach}(k,t)$  is the attachment probability.

For the original model:

$$P_{\text{attach}}(\text{node } i,t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{\text{max}}(t)} kN_k(t)}$$

where  $N(t)=m_0+t$  is # nodes at time t and  $N_k(t)$  is # degree k nodes at time t.

Sublinear attach

Superlinear attachment kernels

# Approximate analysis

When (N+1)th node is added, the expected increase in the degree of node i is

$$E(k_{i,N+1} - k_{i,N}) \simeq m \frac{k_{i,N}}{\sum_{j=1}^{N(t)} k_j(t)}.$$

- Assumes probability of being connected to is small.
- Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.
- $\Leftrightarrow$  Approximate  $k_{i,N+1}-k_{i,N}$  with  $\frac{\mathrm{d}}{\mathrm{d}t}k_{i,t}$ :

$$\frac{\mathrm{d}}{\mathrm{d}t} k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where  $t = N(t) - m_0$ .

Model details

Analysis

A more plausible mechanism

Krapivsky & Redner's model

Generalized model

Analysis

Universality?

Sublinear attachment kernels

Nutsilei

Deal with denominator: each added node brings m new edges.

$$\div \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

The node degree equation now simplifies:

$$\frac{\mathrm{d}}{\mathrm{d}t}k_{i,t} = m\frac{k_i(t)}{\sum_{j=1}^{N(t)}k_j(t)} = m\frac{k_i(t)}{2mt} = \frac{1}{2t}k_i(t)$$

Rearrange and solve:

$$\frac{\mathrm{d}k_i(t)}{k_i(t)} = \frac{\mathrm{d}t}{2t} \Rightarrow \boxed{k_i(t) = c_i t^{1/2}.}$$

 $\mathbb{A}$  Next find  $c_i$  ...

#### The PoCSverse Scale-free networks 17 of 57

Scale-free networks

Analysis

Know ith node appears at time

$$t_{i, \text{start}} = \left\{ \begin{array}{ll} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{array} \right.$$

So for  $i > m_0$  (exclude initial nodes), we must have

$$k_i(t) = m \left(\frac{t}{t_{i,\mathrm{start}}}\right)^{1/2} \text{ for } t \geq t_{i,\mathrm{start}}.$$

First-mover advantage: Early nodes do best.

Scale-free networks

Analysis

Analysis

## We are already at the Zipf distribution:

Degree of node i is the size of the ith ranked node:

$$k_i(t) = m \left(\frac{t}{t_{i,\mathrm{start}}}\right)^{1/2} \text{ for } t \geq t_{i,\mathrm{start}}.$$

From before:

$$t_{i, \text{start}} = \left\{ \begin{array}{ll} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{array} \right.$$

so  $t_{i,\text{start}} \sim i$  which is the rank.

We then have:

$$k_i \propto i^{-1/2} = i^{-\alpha}.$$

 $\alpha = 1/(\gamma - 1)$  or  $\gamma = 1 + 1/\alpha$  then gives

$$\gamma = 1 + 1/(1/2) = 3.$$

### Analysis

Analysis

Sublinear attachment kernels

Nutshell

# Degree distribution

& So what's the degree distribution at time t?

Use fact that birth time for added nodes is distributed uniformly between time 0 and t:

$$\mathbf{Pr}(t_{i, \text{start}}) \mathrm{d}t_{i, \text{start}} \simeq \frac{\mathrm{d}t_{i, \text{start}}}{t}$$

Also use

$$k_i(t) = m \left(\frac{t}{t_{i, \mathrm{start}}}\right)^{1/2} {\Longrightarrow} t_{i, \mathrm{start}} = \frac{m^2 t}{k_i(t)^2}.$$

Transform variables—Jacobian:

$$\frac{\mathrm{d}t_{i,\mathrm{start}}}{\mathrm{d}k_i} = -2\frac{m^2t}{k_i(t)^3}.$$

#### The PoCSverse Scale-free networks 21 of 57

Scale-free networks

Analysis

Analysis

## Degree distribution

$$\mathbf{Pr}(k_i)\mathrm{d}k_i = \mathbf{Pr}(t_{i,\mathrm{start}})\mathrm{d}t_{i,\mathrm{start}}$$

$$= \mathbf{Pr}(t_{i, \mathrm{start}}) \mathrm{d}k_i \, \left| \frac{\mathrm{d}t_{i, \mathrm{start}}}{\mathrm{d}k_i} \right|$$

$$=\frac{1}{t}\mathrm{d}k_i\,2\frac{m^2t}{k_i(t)^3}$$

$$=2\frac{m^2}{k_i(t)^3}\mathrm{d}k_i$$

$$\propto k_i^{-3} \mathrm{d} k_i$$
 .

Analysis

Sublinear attachment kernels

## Degree distribution

We thus have a very specific prediction of  $\mathbf{Pr}(k) \sim k^{-\gamma}$  with  $\gamma = 3$ .

A Typical for real networks:  $2 < \gamma < 3$ .

Range true more generally for events with size distributions that have power-law tails.

 $\stackrel{?}{\leqslant}$  2 <  $\gamma$  < 3: finite mean and 'infinite' variance (wild)

& In practice,  $\gamma < 3$  means variance is governed by upper cutoff.

## Things to do and questions

Nary attachment kernel.

Wary mechanisms:

- 1. Add edge deletion
- 2. Add node deletion
- 3. Add edge rewiring

Deal with directed versus undirected networks.

Marginet Are there distinct universality classes for these networks?

Q.: Do we need preferential attachment and growth?

🔾 .: Do model details matter? Maybe ...

#### The PoCSverse Scale-free networks 26 of 57

Scale-free networks

### Analysis

### Preferential attachment

Let's look at preferential attachment (PA) a little more closely.

A implies arriving nodes have complete knowledge of the existing network's degree distribution.

 $\Leftrightarrow$  For example: If  $P_{\rm attach}(k) \propto k$ , we need to determine the constant of proportionality.

🚷 We need to know what everyone's degree is...

A is ∴ an outrageous assumption of node capability.

But a very simple mechanism saves the day...

Cobustness

Generalized model

Llaimenalin

Sublinear att

Superlinear attachment kernels

Nutsh

## Preferential attachment through randomness

Now add an extra step: new nodes then connect to some of their friends' friends.

& Can also do this at random.

Assuming the existing network is random, we know probability of a random friend having degree k is

$$Q_k \propto kP_k$$

So rich-gets-richer scheme can now be seen to work in a natural way.

from Albert et al., 2000

Scale-free networks are thus robust to random failures yet fragile to targeted ones.

All very reasonable: Hubs are a big deal.

But: next issue is whether hubs are vulnerable or not.

Representing all webpages as the same size node is obviously a stretch (e.g., google vs. a random person's webpage)

Most connected nodes are either:

- 1. Physically larger nodes that may be harder to 'target'
- 2. or subnetworks of smaller, normal-sized nodes.

Need to explore cost of various targeting schemes.

The PoCSverse Scale-free networks 33 of 57

Scale-free networks

### Robustness

### Not a robust paper:

"The "Robust yet Fragile" nature of the Internet" Doyle et al.,

Proc. Natl. Acad. Sci., 2005, 14497-14502, 2005. [?]

HOT networks versus scale-free networks

Same degree distributions, different arrangements.

Doyle et al. take a look at the actual Internet.

The PoCSverse Scale-free networks 34 of 57

Scale-free networks

Robustness

## Fooling with the mechanism:

2001: Krapivsky & Redner (KR) [?] explored the general attachment kernel:

$$\mathbf{Pr}(\mathrm{attach}\ \mathrm{to}\ \mathrm{node}\ i) \propto A_k = k_i^{\nu}$$

where  $A_k$  is the attachment kernel and  $\nu > 0$ .

KR also looked at changing the details of the attachment kernel.

#### The PoCSverse Scale-free networks 37 of 57

Scale-free networks

Generalized model

We'll follow KR's approach using rate equations <a>C</a>.

A Here's the set up:

$$\frac{\mathrm{d}N_k}{\mathrm{d}t} = \frac{1}{A}\left[A_{k-1}N_{k-1} - A_kN_k\right] + \delta_{k1}$$

where  $N_k$  is the number of nodes of degree k.

- 1. One node with one link is added per unit time.
- 2. The first term corresponds to degree k-1 nodes becoming degree k nodes.
- 3. The second term corresponds to degree k nodes becoming degree k-1 nodes.
- 4. A is the correct normalization (coming up).
- 5. Seed with some initial network (e.g., a connected pair)
- 6. Detail:  $A_0 = 0$

#### The PoCSverse Scale-free networks 38 of 57

Scale-free networks

Generalized model

Sublinear attachment kernels

In general, probability of attaching to a specific node of degree k at time t is

$$\mathbf{Pr}(\text{attach to node } i) = \frac{A_k}{A(t)}$$

where 
$$A(t) = \sum_{k=1}^{\infty} A_k N_k(t)$$
.

& E.g., for BA model,  $A_k = k$  and  $A = \sum_{k=1}^{\infty} kN_k(t)$ .

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) = 2t$$

since one edge is being added per unit time.

Detail: we are ignoring initial seed network's edges.

#### The PoCSverse Scale-free networks 40 of 57

Scale-free networks

Sublinear attachment kernels

$$\frac{\mathrm{d}N_k}{\mathrm{d}t} = \frac{1}{A}\left[A_{k-1}N_{k-1} - A_kN_k\right] + \delta_{k1}$$

becomes

$$\frac{\mathrm{d}N_k}{\mathrm{d}t} = \frac{1}{2t}\left[(k-1)N_{k-1} - kN_k\right] + \delta_{k1}$$

- As for BA method, look for steady-state growing solution:  $N_k = n_k t$ .
- $lap{R}$  We replace  $\mathrm{d}N_k/\mathrm{d}t$  with  $\mathrm{d}n_kt/\mathrm{d}t=n_k$ .
- We arrive at a difference equation:

$$n_k = \frac{1}{2 \textcolor{red}{t}} \left[ (k-1) n_{k-1} \textcolor{red}{t} - k n_k \textcolor{red}{t} \right] + \delta_{k1}$$
