Inverse Gaussian

Size distributions—Assignment 1 recap:

The sizes of many systems' elements appear to obey an inverse power-law size distribution:

$$P(\text{size} = x) \sim c x^{-\gamma}$$

where $x_{\min} < x < x_{\max}$

and $\gamma > 1$

- ▶ x_{\min} = lower cutoff
- ▶ x_{\max} = upper cutoff
- ▶ Negative linear relationship in log-log space:

$$\log P(x) = \log c - \gamma \log x$$

Size distributions

- ▶ Usually, only the tail of the distribution obeys a power law:

$$P(x) \sim c x^{-\gamma} \text{ for } x \text{ large.}$$

- ▶ Still use term 'power law distribution'

Size distributions

Many systems have discrete sizes k :

- ▶ Word frequency
- ▶ Node degree (as we have seen): # hyperlinks, etc.
- ▶ number of citations for articles, court decisions, etc.

$$P(k) \sim c k^{-\gamma}$$

where $k_{\min} \leq k \leq k_{\max}$

Size distributions

Power law size distributions are sometimes called Pareto distributions (☹) after Italian scholar Vilfredo Pareto.

- ▶ Pareto noted wealth in Italy was distributed unevenly (80–20 rule).
- ▶ Term used especially by economists

Moments

Standard deviation is a mathematical convenience!:

- ▶ Variance is nice analytically...
- ▶ Another measure of distribution width:

$$\text{Mean average deviation (MAD)} = \langle |x - \langle x \rangle| \rangle$$

- ▶ For a pure power law with $2 < \gamma < 3$:

$$\langle |x - \langle x \rangle| \rangle \text{ is finite.}$$

- ▶ But MAD is unpleasant analytically...
- ▶ We still speak of infinite 'width' if $\gamma < 3$.

Devilish power law distribution details:

From assignment 1, we know many nasty things.

Exhibit A:

Given $P(x) = cx^{-\gamma}$ with $0 < x_{\min} < x < x_{\max}$, the mean is:

$$\langle x \rangle = \frac{c}{2-\gamma} \left(x_{\max}^{2-\gamma} - x_{\min}^{2-\gamma} \right).$$

- ▶ Mean 'blows up' with upper cutoff if $\gamma < 2$.
- ▶ Mean depends on lower cutoff if $\gamma > 2$.
- ▶ $\gamma < 2$: Typical sample is large.
- ▶ $\gamma > 2$: Typical sample is small.

How sample sizes grow...

Given $P(x) \sim cx^{-\gamma}$:

- ▶ We can show that after n samples, we expect the largest sample to be

$$x_1 \gtrsim c'n^{1/(\gamma-1)}$$

- ▶ Sampling from a finite-variance distribution gives a much slower growth with n .
- ▶ e.g., for $P(x) = \lambda e^{-\lambda x}$, we find

$$x_1 \gtrsim \frac{1}{\lambda} \ln n.$$

And in general...

Moments:

- ▶ All moments depend only on cutoffs.
- ▶ No internal scale that dominates/matters.
- ▶ Compare to a Gaussian, exponential, etc.

For many real size distributions: $2 < \gamma < 3$

- ▶ mean is finite (depends on lower cutoff)
- ▶ $\sigma^2 =$ variance is 'infinite' (depends on upper cutoff)
- ▶ Width of distribution is 'infinite'
- ▶ If $\gamma > 3$, distribution is less terrifying and may be easily confused with other kinds of distributions.

Size distributions

Examples:

- ▶ Earthquake magnitude (Gutenberg Richter law): $P(M) \propto M^{-3}$
- ▶ Number of war deaths: $P(d) \propto d^{-1.8}$
- ▶ Sizes of forest fires
- ▶ Sizes of cities: $P(n) \propto n^{-2.1}$
- ▶ Number of links to and from websites

Size distributions

Examples:

- ▶ Number of citations to papers: $P(k) \propto k^{-3}$.
- ▶ Individual wealth (maybe): $P(W) \propto W^{-2}$.
- ▶ Distributions of tree trunk diameters: $P(d) \propto d^{-2}$.
- ▶ The gravitational force at a random point in the universe: $P(F) \propto F^{-5/2}$.
- ▶ Diameter of moon craters: $P(d) \propto d^{-3}$.
- ▶ Word frequency: e.g., $P(k) \propto k^{-2.2}$ (variable)

Note: Exponents range in error; see M.E.J. Newman

Size distributions

Power-law distributions are..

- ▶ often called 'heavy-tailed'
- ▶ or said to have 'fat tails'

Important!:

- ▶ Inverse power laws aren't the only ones:
 - ▶ lognormals, stretched exponentials, ...

Zipfian rank-frequency plots

Zipf's way:

- ▶ s_r = the size of the r th ranked object.
- ▶ $r = 1$ corresponds to the largest size.
- ▶ Example: s_1 could be the frequency of occurrence of the most common word in a text.
- ▶ Zipf's observation:

$$s_r \propto r^{-\alpha}$$

Size distributions

Observe:

- ▶ $NP_{\geq}(x)$ = the number of objects with size at least x where N = total number of objects.
- ▶ If an object has size x_r , then $NP_{\geq}(x_r)$ is its rank r .
- ▶ So

$$x_r \propto r^{-\alpha} = (NP_{\geq}(x_r))^{-\alpha}$$

$$\propto x_r^{(-\gamma+1)(-\alpha)}$$

Since $P_{\geq}(x) \sim x^{-\gamma+1}$,

$$\alpha = \frac{1}{\gamma - 1}$$

- ▶ A rank distribution exponent of $\alpha = 1$ corresponds to a size distribution exponent $\gamma = 2$.
