Size distributions

Usually, only the tail of the distribution obeys a power law:

$$P(x) \sim c x^{-\gamma} \text{ for } x \text{ large.}$$

- ▶ Still use term 'power law distribution.'
- ▶ Other terms:
 - ▶ Fat-tailed distributions.
 - ▶ Heavy-tailed distributions.

Beware:

- ▶ Inverse power laws aren't the only ones: lognormals (田), Weibull distributions (田), ...

Size distributions

Many systems have discrete sizes k :

- ▶ Word frequency
- ▶ Node degree in networks: # friends, # hyperlinks, etc.
- ▶ # citations for articles, court decisions, etc.

$$P(k) \sim c k^{-\gamma}$$

where $k_{\min} \leq k \leq k_{\max}$

- ▶ Obvious fail for $k = 0$.
- ▶ Again, typically a description of distribution's tail.

5 of 36

Size distributions

The sizes of many systems' elements appear to obey an inverse power-law size distribution:

$$P(\text{size} = x) \sim c x^{-\gamma}$$

where $0 < x_{\min} < x < x_{\max}$
and $\gamma > 1$

- ▶ Exciting class exercise: sketch this function.
- ▶ x_{\min} = lower cutoff
- ▶ x_{\max} = upper cutoff
- ▶ Negative linear relationship in log-log space:

$$\log_{10} P(x) = \log_{10} c - \gamma \log_{10} x$$

- ▶ We use base 10 because we are good people.

The statistics of surprise:

From: "Quake Moves Japan Closer to U.S. and Alters Earth's Spin" (田) by Kenneth Chang, March 13, 2011, NYT:

What is perhaps most surprising about the Japan earthquake is how misleading history can be. In the past 300 years, no earthquake nearly that large—nothing larger than magnitude eight—had struck in the Japan subduction zone. That, in turn, led to assumptions about how large a tsunami might strike the coast.

"It did them a giant disservice," said Dr. Stein of the geological survey. That is not the first time that the earthquake potential of a fault has been underestimated. Most geophysicists did not think the Sumatra fault could generate a magnitude 9.1 earthquake, ...

Great:

Two things we have poor cognitive understanding of:

- Probability
 - Ex. The Monty Hall Problem (田)
 - Ex. Son born on Tuesday (田).
- Logarithmic scales.

On counting and logarithms:

- Listen to Radiolab's "Numbers." (田)
- Later: Benford's Law (田).

FIG. 4 Cumulative distributions or "rank-frequency plots" of twelve quantities required to follow power laws. The distributions in Table 4. Source references for the data are given in the text. (a) Number of occurrences of words in the novel *Moby Dick* by Herman Melville. (b) Number of citations to research papers published in 1984, from time of publication until 1999. (c) Number of hits to the website of the University of Vermont in 2000. (d) Numbers of copies of bestselling books sold in the US between 1895 and 1995. (e) Number of calls received by AT&T from telephone numbers in the US between 1980 and 1990. (f) Magnitudes of earthquakes between 1900 and 1990. (g) Diameter of craters on the moon. Vertical axis is measured per square kilometer. (h) Peak intensity of earthquakes between 1900 and 1990. (i) Intensity of earthquakes between 1900 and 1990. (j) Aggregate net worth in dollars of the richest individuals in the US in October 2002. (k) Frequency of occurrence of family names in the US in the year 1996. (l) Population of US cities in the year 2000.

$$x^{-\gamma}$$

And in general...

Moments:

- ▶ All moments depend only on cutoffs.
- ▶ **No internal scale** that dominates/matters.
- ▶ Compare to a Gaussian, exponential, etc.

For many real size distributions: $2 < \gamma < 3$

- ▶ mean is finite (depends on lower cutoff)
- ▶ $\sigma^2 =$ variance is 'infinite' (depends on upper cutoff)
- ▶ Width of distribution is 'infinite'
- ▶ If $\gamma > 3$, distribution is less terrifying and may be easily confused with other kinds of distributions.

$$x^{-\gamma}$$

Size distributions

Power law size distributions are sometimes called **Pareto distributions** (田) after Italian scholar **Vilfredo Pareto**. (田)

- ▶ Pareto noted wealth in Italy was distributed unevenly (80–20 rule; misleading).
- ▶ Term used especially by practitioners of the **Dismal Science** (田).

$$x^{-\gamma}$$

Moments

Standard deviation is a mathematical convenience:

- ▶ Variance is nice analytically...
- ▶ Another measure of distribution width:

$$\text{Mean average deviation (MAD)} = \langle |x - \langle x \rangle| \rangle$$

- ▶ For a pure power law with $2 < \gamma < 3$:

$$\langle |x - \langle x \rangle| \rangle \text{ is finite.}$$

- ▶ But MAD is mildly unpleasant analytically...
- ▶ We still speak of infinite 'width' if $\gamma < 3$.

$$x^{-\gamma}$$

Devilish power law distribution details:

Exhibit A:

- ▶ Given $P(x) = cx^{-\gamma}$ with $0 < x_{\min} < x < x_{\max}$, the mean is ($\gamma \neq 2$):

$$\langle x \rangle = \frac{c}{2-\gamma} \left(x_{\max}^{2-\gamma} - x_{\min}^{2-\gamma} \right).$$

- ▶ Mean 'blows up' with upper cutoff if $\gamma < 2$.
- ▶ Mean depends on lower cutoff if $\gamma > 2$.
- ▶ $\gamma < 2$: Typical sample is large.
- ▶ $\gamma > 2$: Typical sample is small.

$$x^{-\gamma}$$

How sample sizes grow...

Given $P(x) \sim cx^{-\gamma}$:

- ▶ We can show that after n samples, we expect the largest sample to be

$$x_1 \gtrsim c'n^{1/(\gamma-1)}$$

- ▶ Sampling from a finite-variance distribution gives a much slower growth with n .
- ▶ e.g., for $P(x) = \lambda e^{-\lambda x}$, we find

$$x_1 \gtrsim \frac{1}{\lambda} \ln n.$$

Zipfian rank-frequency plots

Zipf's way:

- Given a collection of entities, rank them by size, largest to smallest.
- x_r = the size of the r th ranked entity.
- $r = 1$ corresponds to the largest size.
- Example: x_1 could be the frequency of occurrence of the most common word in a text.
- Zipf's observation:

$$x_r \propto r^{-\alpha}$$

$$x^{-\gamma}$$

Size distributions

Brown Corpus (1,015,945 words):

CCDF:

Zipf (axes flipped):

- ▶ The, of, and, to, a, ... = 'objects'
- ▶ 'Size' = word frequency
- ▶ **Beep:** CCDF and Zipf plots are related...

Observe:

- ▶ $NP_{\geq}(x)$ = the number of objects with size at least x where N = total number of objects.
- ▶ If an object has size x_r , then $NP_{\geq}(x_r)$ is its rank r .
- ▶ So

$$x_r \propto r^{-\alpha} = (NP_{\geq}(x_r))^{-\alpha}$$

$$\propto x_r^{(-\gamma+1)(-\alpha)} \text{ since } P_{\geq}(x) \sim x^{-\gamma+1}.$$

We therefore have $1 = (-\gamma + 1)(-\alpha)$ or:

$$\alpha = \frac{1}{\gamma - 1}$$

- ▶ A rank distribution exponent of $\alpha = 1$ corresponds to a size distribution exponent $\gamma = 2$.

The Don. (田)

Extreme deviations in test cricket:

- ▶ Don Bradman's batting average (田) = **166%** next best.
