## lognormals

The lognormal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

- ▶  $\ln x$  is distributed according to a normal distribution with mean  $\mu$  and variance  $\sigma$ .
- ▶ Appears in economics and biology where growth increments are distributed normally.

# lognormals

- ▶ Standard form reveals the mean  $\mu$  and variance  $\sigma^2$  of the underlying normal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

- ▶ For lognormals:

$$\mu_{\text{lognormal}} = e^{\mu + \frac{1}{2}\sigma^2}, \quad \text{median}_{\text{lognormal}} = e^\mu,$$

$$\sigma_{\text{lognormal}} = (e^{\sigma^2} - 1)e^{2\mu + \sigma^2}, \quad \text{mode}_{\text{lognormal}} = e^{\mu - \sigma^2}.$$

- ▶ All moments of lognormals are **finite**.

# Confusion

What's happening:

$$\ln P(x) = \ln \left\{ \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) \right\}$$

$$= -\ln x - \ln \sqrt{2\pi}\sigma - \frac{(\ln x - \mu)^2}{2\sigma^2}$$

$$= -\frac{1}{2\sigma^2}(\ln x)^2 + \left(\frac{\mu}{\sigma^2} - 1\right) \ln x - \ln \sqrt{2\pi}\sigma - \frac{\mu^2}{2\sigma^2}.$$

If the first term is relatively small,

$$\ln P(x) \sim -\left(1 - \frac{\mu}{\sigma^2}\right) \ln x + \text{const.} \Rightarrow \gamma = 1 - \frac{\mu}{\sigma^2}$$

# Derivation from a normal distribution

Take  $Y$  as distributed normally:

- ▶

$$P(y)dy = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(y - \mu)^2}{2\sigma^2}\right) dy$$

Set  $Y = \ln X$ :

- ▶ Transform according to  $P(x)dx = P(y)dy$ :

- ▶

$$\frac{dy}{dx} = 1/x \Rightarrow dy = dx/x$$

- ▶

$$\Rightarrow P(x)dx = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) dx$$

# Confusion

- ▶ If  $\mu < 0$ ,  $\gamma > 1$  which is totally cool.
- ▶ If  $\mu > 0$ ,  $\gamma < 1$ , not so much.
- ▶ If  $\sigma^2 \gg 1$  and  $\mu$ ,

$$\ln P(x) \sim -\ln x + \text{const.}$$

- ▶ Expect -1 scaling to hold until  $(\ln x)^2$  term becomes significant compared to  $(\ln x)$ :

$$-\frac{1}{2\sigma^2}(\ln x)^2 \approx 0.05 \left(\frac{\mu}{\sigma^2} - 1\right) \ln x$$

$$\Rightarrow \log_{10} x \lesssim 0.05 \times 2(\sigma^2 - \mu) \log_{10} e \approx 0.05(\sigma^2 - \mu)$$

- ▶  $\Rightarrow$  If you find a -1 exponent, you may have a lognormal distribution...

# Confusion between lognormals and pure power laws

Near agreement over four orders of magnitude!

- ▶ For lognormal (blue),  $\mu = 0$  and  $\sigma = 10$ .
- ▶ For power law (red),  $\gamma = 1$  and  $c = 0.03$ .

# Generating lognormals:

Random multiplicative growth:

- ▶

$$x_{n+1} = r x_n$$

where  $r > 0$  is a random growth variable

- ▶ (Shrinkage is allowed)
- ▶ In log space, growth is by addition:

$$\ln x_{n+1} = \ln r + \ln x_n$$

- ▶  $\Rightarrow \ln x_n$  is normally distributed
- ▶  $\Rightarrow x_n$  is lognormally distributed

## Lognormals or power laws?

- ▶ Gibrat<sup>[2]</sup> (1931) uses preceding argument to explain lognormal distribution of firm sizes ( $\gamma \approx 1$ ).
- ▶ But Robert Axtell<sup>[1]</sup> (2001) shows a power law fits the data very well with  $\gamma = 2$ , not  $\gamma = 1$  (!)
- ▶ Problem of data censusing (missing small firms).

$$\text{Freq} \propto (\text{size})^{-\gamma}$$

$$\gamma \approx 2$$

- ▶ One piece in Gibrat's model seems okay empirically: Growth rate  $r$  appears to be independent of firm size.<sup>[1]</sup>

## The second tweak

### Ages of firms/people/... may not be the same

- ▶ Allow the number of updates for each size  $x_i$  to vary
- ▶ Example:  $P(t)dt = ae^{-at}dt$  where  $t = \text{age}$ .
- ▶ Back to no bottom limit: each  $x_i$  follows a lognormal
- ▶ Sizes are distributed as<sup>[6]</sup>

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln x - \mu)^2}{2t}\right) dt$$

(Assume for this example that  $\sigma \sim t$  and  $\mu = \ln m$ )

- ▶ Now averaging different lognormal distributions.

## An explanation

- ▶ Axtel cites Malcai et al.'s (1999) argument<sup>[5]</sup> for why power laws appear with exponent  $\gamma \approx 2$
- ▶ The set up:  $N$  entities with size  $x_i(t)$
- ▶ Generally:

$$x_i(t+1) = rx_i(t)$$

where  $r$  is drawn from some happy distribution

- ▶ Same as for lognormal but one extra piece.
- ▶ Each  $x_i$  cannot drop too low with respect to the other sizes:

$$x_i(t+1) = \max(rx_i(t), c \langle x_i \rangle)$$

## Averaging lognormals

- ▶

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln \frac{x}{m})^2}{2t}\right) dt$$

- ▶ Insert fabulous calculation (team is spared).
- ▶ Some enjoyable suffering leads to:

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda} (\ln \frac{x}{m})^2}$$

## Some math later...

Insert question from assignment 7 [↗](#)

- ▶ Find  $P(x) \sim x^{-\gamma}$
- ▶ where  $\gamma$  is implicitly given by

$$N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[ \frac{(c/N)^{\gamma-1} - 1}{(c/N)^{\gamma-1} - (c/N)} \right]$$

$N = \text{total number of firms.}$

- ▶ Now, if  $c/N \ll 1$  and  $\gamma > 2$   $N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[ \frac{-1}{-(c/N)} \right]$

- ▶ Which gives  $\gamma \sim 1 + \frac{1}{1 - c}$

- ▶ Groovy...  $c \text{ small} \Rightarrow \gamma \approx 2$

## The second tweak

- ▶

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda} (\ln \frac{x}{m})^2}$$

- ▶ Depends on sign of  $\ln \frac{x}{m}$ , i.e., whether  $\frac{x}{m} > 1$  or  $\frac{x}{m} < 1$ .

- ▶

$$P(x) \propto \begin{cases} x^{-1+\sqrt{2\lambda}} & \text{if } \frac{x}{m} < 1 \\ x^{-1-\sqrt{2\lambda}} & \text{if } \frac{x}{m} > 1 \end{cases}$$

- ▶ 'Break' in scaling (not uncommon)
- ▶ Double-Pareto distribution [↗](#)
- ▶ First noticed by Montroll and Shlesinger<sup>[7, 8]</sup>
- ▶ Later: Huberman and Adamic<sup>[3, 4]</sup>: Number of pages per website

## Summary of these exciting developments:

- ▶ Lognormals and power laws can be **awfully** similar
- ▶ Random Multiplicative Growth leads to lognormal distributions
- ▶ Enforcing a minimum size leads to a power law tail
- ▶ With no minimum size but a distribution of lifetimes, the double Pareto distribution appears
- ▶ Take-home message: Be careful out there...
