Random walks on networks—basics:

200 4 of 9

#### Where is Barry?

Consider simple undirected, ergodic (strongly connected) networks.

As usual, represent network by adjacency matrix A where

> $a_{ij} = 1$  if *i* has an edge leading to *j*,  $a_{ij} = 0$  otherwise.

Barry is at node *j* at time *t* with probability *p<sub>j</sub>(t)*.
In the next time step, he randomly lurches toward one of *j*'s neighbors.

Barry arrives at node *i* from node *j* with probability  $\frac{1}{k_i}$  if an edge connects *j* to *i*.

🚳 Equation-wise:

$$p_i(t+1) = \sum_{j=1}^n \frac{1}{k_j} a_{ji} p_j(t).$$

where  $k_j$  is j's degree. Note:  $k_i = \sum_{i=1}^n a_{ij}$ .

Random walks on networks

## Inebriation and diffusion:

2

COcoNuTS

Random walks on networks

Excellent observation: The same equation applies for stuff moving around a network, such that at each time step all material at node *i* is sent to its neighbors.

 $x_i(t)$  = amount of stuff at node *i* at time *t*.

$$x_i(t+1) = \sum_{j=1}^n \frac{1}{k_j} a_{ji} x_j(t).$$

Andom walking is equivalent to diffusion C.

## Where is Barry?

Solution Linear algebra-based excitement:  $p_i(t+1) = \sum_{j=1}^n a_{ji} \frac{1}{k_j} p_j(t) \text{ is more usefully viewed}$ as

 $\vec{p}(t+1) = A^{\mathsf{T}} K^{-1} \vec{p}(t)$ 

where  $[K_{ij}] = [\delta_{ij}k_i]$  has node degrees on the main diagonal and zeros everywhere else.

So... we need to find the dominant eigenvalue of  $A^{\mathsf{T}}K^{-1}$ .

- Expect this eigenvalue will be 1 (doesn't make sense for total probability to change).
- The corresponding eigenvector will be the limiting probability distribution (or invariant measure).
- Extra concerns: multiplicity of eigenvalue = 1, and network connectedness.

#### Where is Barry?

🛞 By inspection, we see that

COCONUTS

Random walks on networks

 $\vec{p}(\infty) = \frac{1}{\sum_{i=1}^{n} k_i} \vec{k}$ satisfies  $\vec{p}(\infty) = A^{\mathsf{T}} K^{-1} \vec{p}(\infty)$  with eigenvalue 1.  $\bigotimes$  We will find Barry at node *i* with probability proportional to its degree  $k_i$ . Beautiful implication: probability of finding Barry travelling along any edge is uniform. Diffusion in real space smooths things out. On networks, uniformity occurs on edges. So in fact, diffusion in real space is about the edges too but we just don't see that.

Random walks on networks

Goodness:  $A^{\mathsf{T}}K^{-1}$  is similar to a real symmetric matrix if  $A = A^{\mathsf{T}}$ .

Solution Consider the transformation  $M = K^{-1/2}$ :

$$K^{-1/2} A^{\mathsf{T}} K^{-1} K^{1/2} = K^{-1/2} A^{\mathsf{T}} K^{-1/2}.$$

Since  $A^{\mathsf{T}} = A$ , we have

 $(K^{-1/2}AK^{-1/2})^{\mathsf{T}} = K^{-1/2}AK^{-1/2}.$ 

Upshot: A<sup>T</sup>K<sup>-1</sup> = AK<sup>-1</sup> has real eigenvalues and a complete set of orthogonal eigenvectors.
Can also show that maximum eigenvalue magnitude is indeed 1.
