🗞 Imagine a single random walker moving around

Where  $f \in \mathcal{B}_{i}$  start walker at node j and take time to be

Where  $p_i(t)$  as the probability that at time step t, our walker is at node i.  $a_{it} = 0$  otherwise. We want to characterize the evolution of  $\vec{p}(t)$ . BRATE TO A BEAT AND A CONTRACT AND

 $p_i(t+1) = \sum_{j=1}^n \frac{1}{k_j} a_{ji} p_j(t).$

COcoNuTS

Random walks on networks

Solution: The same equation applies for stuff moving around a network, such that at each time step all material at node i is sent to its neighbors.

$$x_i(t+1) = \sum_{j=1}^n \frac{1}{k_j} a_{ji} x_j(t).$$

Random walking is equivalent to diffusion C.

Other pieces:

- Solution Goodness:  $A^{\mathsf{T}}K^{-1}$  is similar to a real symmetric matrix if  $A = A^{\mathsf{T}}$ .
- $\bigotimes$  Consider the transformation  $M = K^{-1/2}$ :

 $K^{-1/2} \mathbf{A}^{\mathsf{T}} \mathbf{K}^{-1} K^{1/2} = K^{-1/2} \mathbf{A}^{\mathsf{T}} K^{-1/2}.$ 

Since  $A^{\mathsf{T}} = A$ , we have

$$(K^{-1/2}AK^{-1/2})^{\mathsf{T}} = K^{-1/2}AK^{-1/2}.$$

- Solution Upshot:  $A^{\mathsf{T}}K^{-1} = AK^{-1}$  has real eigenvalues and a complete set of orthogonal eigenvectors.
- Can also show that maximum eigenvalue magnitude is indeed 1.

Random walks on networks

# Where is Barry?

 $\begin{aligned} & \underset{p_i(t+1) = \sum_{j=1}^n a_{ji} \frac{1}{k_j} p_j(t) \text{ is more usefully viewed} \\ & \underset{p_i(t+1) = A^\mathsf{T} K^{-1} \vec{p}(t) \end{aligned}$ 

where  $[K_{ij}] = [\delta_{ij}k_i]$  has node degrees on the main diagonal and zeros everywhere else.

- So... we need to find the dominant eigenvalue of  $A^{\mathsf{T}}K^{-1}$ .
- Expect this eigenvalue will be 1 (doesn't make sense for total probability to change).
- The corresponding eigenvector will be the limiting probability distribution (or invariant measure).
- Extra concerns: multiplicity of eigenvalue = 1, and network connectedness.

# Where is Barry?

🗞 By inspection, we see that

$$\vec{p}(\infty) = \frac{1}{\sum_{i=1}^{n} k_i} \vec{k}$$

satisfies  $\vec{p}(\infty) = A^{\mathsf{T}} K^{-1} \vec{p}(\infty)$  with eigenvalue 1.

- & We will find Barry at node i with probability proportional to its degree  $k_i$ .
- Beautiful implication: probability of finding Barry travelling along any edge is uniform.
- $\circledast$  Diffusion in real space smooths things out.
- line the second second
- So in fact, diffusion in real space is about the edges too but we just don't see that.
