少 Q (> 1 of 63

Basic questions about contagion

- How many types of contagion are there?
- How can we categorize real-world contagions?
- & Can we connect models of disease-like and social contagion?
- & Focus: mean field models.

Mathematical Epidemiology (recap)

The standard SIR model [10]

= basic model of disease contagion

Three states:

1. S = Susceptible

2. I = Infective/Infectious

3. R = Recovered or Removed or Refractory

S(t) + I(t) + R(t) = 1

Presumes random interactions (mass-action) principle)

Interactions are independent (no memory)

Discrete and continuous time versions

Reproduction Number R_0

Discrete version:

& Expected number infected by original Infective:

$$R_0 = \beta + (1-r)\beta + (1-r)^2\beta + (1-r)^3\beta + \dots$$

$$=\beta \left(1+(1-r)+(1-r)^2+(1-r)^3+...\right)$$

$$=\beta \frac{1}{1-(1-r)} = \beta/r$$

Similar story for continuous model.

Independent Interaction models

Differential equations for continuous model

$$\frac{\mathsf{d}}{\mathsf{d}t}S = -\beta \underline{IS} + \rho R$$

$$\frac{\mathrm{d}}{\mathrm{d}t}I = \beta \underline{IS} - rI$$

$$\frac{\mathsf{d}}{\mathsf{d}t}R = rI - \rho R$$

 β , r, and ρ are now rates.

Reproduction Number R_0 :

- $\Re R_0$ = expected number of infected individuals resulting from a single initial infective
- \clubsuit Epidemic threshold: If $R_0 > 1$, 'epidemic' occurs.

Independent Interaction models

Example of epidemic threshold:

- Continuous phase transition.
- A Fine idea from a simple model.

Introduction

Independent Interaction models

Interdependent models

Nutshell

Appendix

References

Reproduction Number R_0

Discrete version:

- Set up: One Infective in a randomly mixing population of Susceptibles
- At time t = 0, single infective random bumps into a Susceptible
- \triangle Probability of transmission = β
- \clubsuit At time t=1, single Infective remains infected with probability 1-r
- \clubsuit At time t = k, single Infective remains infected with probability $(1-r)^k$

Simple disease spreading models

Valiant attempts to use SIR and co. elsewhere:

- Adoption of ideas/beliefs (Goffman & Newell, 1964)^[6]
- Spread of rumors (Daley & Kendall, 1964, 1965) [2, 3]
- A Diffusion of innovations (Bass, 1969) [1]
- Spread of fanatical behavior (Castillo-Chávez & Song, 2003)

少 Q № 12 of 63

Granovetter's model (recap of recap)

Action based on perceived behavior of others.

- Two states: S and I.
- Recovery now possible (SIS).
- $\Leftrightarrow \phi$ = fraction of contacts 'on' (e.g., rioting).
- Discrete time, synchronous update.
- This is a Critical mass model.
- Interdependent interaction model.

Some (of many) issues

- Disease models assume independence of infectious events.
- Threshold models only involve proportions: $3/10 \equiv 30/100$.
- Threshold models ignore exact sequence of influences
- Threshold models assume immediate polling.
- Mean-field models neglect network structure
- Network effects only part of story: media, advertising, direct marketing.

models

Generalized model

Basic ingredients:

- A Incorporate memory of a contagious element [4, 5]
- Population of N individuals, each in state S, I, or R.
- Each individual randomly contacts another at each time step.
- $\Leftrightarrow \phi_t$ = fraction infected at time t= probability of contact with infected individual
- \aleph With probability p, contact with infective leads to an exposure.
- \mathbb{A} If exposed, individual receives a dose of size d drawn from distribution f. Otherwise d = 0.

Generalized model—ingredients

 $S \Rightarrow I$

& Individuals 'remember' last T contacts:

$$D_{t,i} = \sum_{t'=t-T+1}^{t} d_i(t')$$

& Infection occurs if individual i's 'threshold' is exceeded:

$$D_{t,i} \geq d_i^*$$

 $\begin{cases} \& \& \end{cases}$ Threshold d_i^* drawn from arbitrary distribution gat t = 0.

COcoNuTS

Introduction

Independent models

Generalized Model

Appendix

References

少 q (~ 16 of 63

Generalized model—ingredients

 $I \Rightarrow R$

When $D_{t,i} < d_i^*$, individual i recovers to state R with probability r.

Once in state R, individuals become susceptible again with probability ρ .

1 if $D_{t,i} < d_i^*$

if $D_{t,i} \ge d_i^*$

1 - r if $D_{t,i} < d_i^*$ 1 if $D_{t,i} \ge d_i^*$

A visual explanation

Generalized mean-field model

Study SIS-type contagion first:

Recovered individuals are immediately susceptible again:

$$\rho = 1$$
.

- Look for steady-state behavior as a function of exposure probability p.
- & Denote fixed points by ϕ^* .

Homogeneous version:

- All individuals have threshold d*
- All dose sizes are equal: d = 1

Simple homogeneous examples

Fixed points for r = 1, $d^* = 1$, and T > 1

- r = 1 means recovery is immediate.
- Rrightarrow T > 1 means individuals remember at least 2 interactions.
- $d^* = 1$ means only one positive interaction in past T interactions will infect individual.
- Effect of individual interactions is independent from effect of others.
- & Call ϕ^* the steady state level of infection.
- Pr(infected) = 1 Pr(uninfected):

$$\phi^* = 1 - (1 - p\phi^*)^T.$$

COcoNuTS

Appendix References

Homogeneous, one hit models:

Fixed points for r < 1, $d^* = 1$, and T = 1:

- r < 1 means recovery is probabilistic.
- T = 1 means individuals forget past interactions.
- $d^* = 1$ means one positive interaction will infect an individual.
- Evolution of infection level:

$$\phi_{t+1} = \underbrace{p\phi_t}_{\mathsf{A}} + \underbrace{\phi_t(1-p\phi_t)}_{\mathsf{b}} \underbrace{(1-r)}_{\mathsf{C}}.$$

- a: Fraction infected between t and t+1, independent of past state or recovery.
- b: Probability of being infected and not being reinfected.
- c: Probability of not recovering.

Homogeneous, one hit models:

Fixed points for r = 1, $d^* = 1$, and T > 1

Closed form expression for φ*:

$$\phi^* = 1 - (1 - p\phi^*)^T.$$

- & Look for critical infection probability p_c .
- \clubsuit As $\phi^* \to 0$, we see

$$\phi^* \simeq pT\phi^* \Rightarrow p_c = 1/T.$$

- Again find continuous phase transition...
- Note: we can solve for p but not ϕ^* :

$$p = (\phi^*)^{-1}[1 - (1 - \phi^*)^{1/T}].$$

Interdependent interaction models

Generalized Model Homogeneous version

Nutshell

Appendix References

少 q (~ 25 of 63

Homogeneous, one hit models:

Fixed points for $r \le 1$, $d^* = 1$, and $T \ge 1$

In general, relevant dose histories are:

$$H_{m+1} = \{\dots, d_{t-T-m-1}, 1, \underbrace{0, 0, \dots, 0, 0}_{m \text{ 0's}}, \underbrace{0, 0, \dots, 0, 0}_{T \text{ 0's}}\}.$$

Overall probabilities for dose histories occurring:

$$P(H_1) = p\phi^* (1 - p\phi^*)^T (1 - r),$$

$$P(H_{m+1}) = \underbrace{p\phi^*}_a \underbrace{(1-p\phi^*)^{T+m}}_b \underbrace{(1-r)^{m+1}}_c.$$

- a: Pr(infection T + m + 1 time steps ago)
- b: Pr(no doses received in T + m time steps since)
- c: $Pr(no\ recovery\ in\ m\ chances)$

Homogeneous, one hit models:

time steps and recovering)

Fixed point equation:

Fixed points for $r \le 1$, $d^* = 1$, and $T \ge 1$

 \Re Pr(recovery) = Pr(seeing no doses for at least T

 $= \mathop{r}\sum_{m=-0}^{\infty} P(H_{T+m}) = \mathop{r}\sum_{m=0}^{\infty} p \phi^* (1 - p \phi^*)^{T+m} (1 - r)^m$

 $= r \frac{p\phi^*(1 - p\phi^*)^T}{1 - (1 - p\phi^*)(1 - r)}.$

 $\phi^* = 1 - \frac{r(1 - p\phi^*)^T}{1 - (1 - p\phi^*)(1 - r)}.$

Homogeneous, multi-hit models:

All right: $d^* = 1$ models correspond to simple disease spreading models.

 \Leftrightarrow Example details: $T=2 \& r=1/2 \Rightarrow p_c=1/3$.

 $\approx \tau = 1/r - 1$ = characteristic recovery time = 1.

Phase transition can be seen as a transcritical

Blue = stable, red = unstable, fixed points.

 $Rrac{1}{8}$ $T + \tau \simeq$ average memory in system = 3.

 \clubsuit What if we allow $d^* \geq 2$?

bifurcation. [11]

Epidemic threshold:

 $\phi^* = 1 - \frac{r(1-p\phi^*)^T}{1-(1-p\phi^*)(1-p\phi^*)}$

 $p_c = 1/(T + \tau)$

Fixed points for $d^* = 1$, r < 1, and $T \ge 1$

- Again first consider SIS with immediate recovery (r = 1)
- Also continue to assume unit dose sizes $(f(d) = \delta(d-1)).$
- \clubsuit To be infected, must have at least d^* exposures in last T time steps.
- Fixed point equation:

$$\phi^* = \sum_{i=d^*}^T {T \choose i} (p\phi^*)^i (1-p\phi^*)^{T-i}.$$

 \clubsuit As always, $\phi^* = 0$ works too.

UNIVERSITY OF

Homogeneous, multi-hit models:

Fixed points for r = 1, $d^* > 1$, and T > 1

- & Exactly solvable for small T.
- \$ e.g., for $d^* = 2$, T = 3:

- Fixed point equation: $3p^2\phi^{*2}(1-p\phi^*)+p^3\phi^{*3}$
- 🙈 See new structure: a saddle node bifurcation [11] appears as p increases.
- $(p_b, \phi^*) = (8/9, 27/32).$

Behavior akin to output of Granovetter's threshold model.

少 Q (~ 37 of 63

Fixed points for r < 1, $d^* > 1$, and $T \ge 1$

- & Determine number of sequences of length m that keep dose load below $d^* = 2$.
- N_a = number of $a = \{0\}$ subsequences.
- \aleph N_b = number of $b = \{1, 0, 0\}$ subsequences.

$$m = N_a \cdot 1 + N_b \cdot 3$$

Possible values for N_b :

$$0, 1, 2, \dots, \left| \frac{m}{3} \right|$$
.

where $|\cdot|$ means floor.

& Corresponding possible values for N_a :

$$m, m-3, m-6, \ldots, m-3 \left\lfloor \frac{m}{3} \right\rfloor$$
.

Fixed points for r < 1, $d^* > 1$, and $T \ge 1$

- \clubsuit How many ways to arrange N_a a's and N_b b's?
- Think of overall sequence in terms of subsequences:

$$\{Z_1, Z_2, \dots, Z_{N_a+N_b}\}$$

- $N_a + N_b$ slots for subsequences.
- & Choose positions of either a's or b's:

$${N_a+N_b\choose N_a}={N_a+N_b\choose N_b}.$$

Fixed points for r < 1, $d^* > 1$, and T > 1

 \clubsuit Total number of allowable sequences of length m:

$$\sum_{N_b=0}^{\lfloor m/3\rfloor} {N_b+N_a\choose N_b} = \sum_{k=0}^{\lfloor m/3\rfloor} {m-2k\choose k}$$

where $k = N_b$ and we have used $m = N_a + 3N_b$.

- $P(a) = (1 p\phi^*) \text{ and } P(b) = p\phi^*(1 p\phi^*)^2$
- Total probability of allowable sequences of length

$$\chi_m(p,\phi^*) = \sum_{k=0}^{\lfloor m/3 \rfloor} {m-2k \choose k} (1-p\phi^*)^{m-k} (p\phi^*)^k.$$

Notation: Write a randomly chosen sequence of a's and b's of length m as $D_m^{a,b}$.

•9 q (≈ 43 of 63

Fixed points for r < 1, $d^* > 1$, and $T \ge 1$

T=2, $d^*=2$

- $r = 0.01, 0.05, 0.10, \dots, 0.3820 \pm 0.0001.$
- Arr No spreading for $r \gtrsim 0.382$.

What we have now:

- Two kinds of contagion processes:
 - 1. Continuous phase transition: SIR-like.
 - 2. Saddle-node bifurcation: threshold model-like.
- $d^* = 1$: spreading from small seeds possible.
- $d^* > 1$: critical mass model.
- Are other behaviors possible?

COcoNuTS Generalized model

- Now allow for general dose distributions (f) and threshold distributions (q).
- & Key quantities:

$$P_k = \int_0^\infty \mathrm{d} d^* g(d^*) P\left(\sum_{j=1}^k d_j \geq d^*\right) \text{ where } 1 \leq k \leq T.$$

- P_k = Probability that the threshold of a randomly selected individual will be exceeded by k doses.
- - P_1 = Probability that <u>one dose</u> will exceed the threshold of a random individual
 - = Fraction of most vulnerable individuals.

Fixed point equation:

$$\phi^* = \sum_{k=1}^T {T \choose k} (p\phi^*)^k (1-p\phi^*)^{T-k} \underline{P_k}$$

 \clubsuit Expand around $\phi^* = 0$ to find when spread from single seed is possible:

Generalized model—heterogeneity, r=1

$$pP_1T \ge 1$$

Wery good:

$$\Rightarrow p_c = 1/(TP_1)$$

1. P_1T is the expected number of vulnerables the initial infected individual meets before recovering.

2. pP_1T is : the expected number of successful

& Observe: p_c may exceed 1 meaning no spreading

infections (equivalent to R_0).

from a small seed.

- Next: Determine slope of fixed point curve at critical point p_c .
- Expand fixed point equation around $(p, \phi^*) = (p_c, 0).$
- \mathfrak{F} Find slope depends on $(P_1 P_2/2)^{[5]}$ (see Appendix).
- Behavior near fixed point depends on whether this slope is
 - 1. positive: $P_1 > P_2/2$ (continuous phase transition)
 - 2. negative: $P_1 < P_2/2$ (discontinuous phase
- Now find three basic universal classes of contagion models...

Heterogeneous case

Example configuration:

- Dose sizes are lognormally distributed with mean 1 and variance 0.433.
- & Memory span: T=10.
- Thresholds are uniformly set at
 - 1. $d_* = 0.5$
 - 2. $d_* = 1.6$
 - 3. $d_* = 3$
- Spread of dose sizes matters, details are not important.

少 Q № 50 of 63

Three universal classes

Epidemic threshold:

 $P_1 > P_2/2 \text{, } p_c = 1/(TP_1) < 1$

Vanishing critical mass: $p_c=1/(TP_1)<1$

Pure critical mass:

 $P_1 < P_2/2$, $p_c = 1/(TP_1) > 1$

 $_{0}^{0}$

- Memory is a natural ingredient.
- Three universal classes of contagion processes:

0.5

p

- 1. I. Epidemic Threshold
- 2. II. Vanishing Critical Mass
- 3. III. Critical Mass

Nutshell (other half)

Depends only on:

or influentials.

- Dramatic changes in behavior possible.
- To change kind of model: 'adjust' memory, recovery, fraction of vulnerable individuals (T, r, ρ , P_1 , and/or P_2).
- To change behavior given model: 'adjust' probability of exposure (p) and/or initial number infected (ϕ_0).

Single seed infects others if $pP_1(T+\tau) \geq 1$.

 \clubsuit If $p_c < 1 \Rightarrow$ contagion can spread from single seed.

2. Fraction of highly vulnerable individuals (P_1).

Details unimportant: Many threshold and dose

vulnerable/gullible population may be more important than a small group of super-spreaders

 \Re Key quantity: $p_c = 1/[P_1(T+\tau)]$

1. System Memory $(T + \tau)$.

distributions give same P_k .

Now allow r < 1:

- \mathbb{R} II-III transition generalizes: $p_c = 1/[P_1(T+\tau)]$ where $\tau = 1/r - 1 =$ expected recovery time
- I-II transition less pleasant analytically.

More complicated models

- Due to heterogeneity in individual thresholds.
- Three classes based on behavior for small seeds.
- Same model classification holds: I, II, and III.
