## Many sources, many sinks

How do we distribute sources?

- Focus on 2-d (results generalize to higher dimensions).
- Sources = hospitals, post offices, pubs, ...
- Key problem:** How do we cope with uneven population densities?
- Obvious: if density is uniform then sources are best distributed **uniformly**.
- Which lattice is optimal? The **hexagonal lattice**
- Q2:** Given population density is uneven, what do we do?
- We'll follow work by Stephan (1977, 1984)<sup>[4, 5]</sup>, Gastner and Newman (2006)<sup>[2]</sup>, Um *et al.* (2009)<sup>[6]</sup>, and work cited by them.

## Optimal source allocation

Solidifying the basic problem

- Given a region with some population distribution  $\rho$ , most likely uneven.
- Given resources to build and maintain  $N$  facilities.
- Q:** How do we locate these  $N$  facilities so as to **minimize the average distance** between an individual's residence and the nearest facility?

"Optimal design of spatial distribution networks"  
Gastner and Newman,  
Phys. Rev. E, **74**, 016117, 2006. [2]

- Approximately optimal location of 5000 facilities.
- Based on 2000 Census data.
- Simulated annealing + Voronoi tessellation.

## Optimal source allocation

- Optimal facility density  $\rho_{\text{fac}}$  vs. population density  $\rho_{\text{pop}}$ .
- Fit is  $\rho_{\text{fac}} \propto \rho_{\text{pop}}^{0.66}$  with  $r^2 = 0.94$ .
- Looking good for a 2/3 power ...

## Optimal source allocation

### Size-density law:

$$\rho_{\text{fac}} \propto \rho_{\text{pop}}^{2/3}$$

- Why?
- Again: Different story to branching networks where there was either one source or one sink.
- Now sources & sinks are distributed throughout region.

## Optimal source allocation

"Territorial Division: The Least-Time Constraint Behind the Formation of Subnational Boundaries"  
G. Edward Stephan,  
Science, **196**, 523-524, 1977. [4]

- We first examine Stephan's treatment (1977) [4, 5]
- "Territorial Division: The Least-Time Constraint Behind the Formation of Subnational Boundaries" (Science, 1977)
- Zipf-like approach: invokes **principle of minimal effort**.
- Also known as the Homer Simpson principle.

## Optimal source allocation

- Consider a region of area  $A$  and population  $P$  with a single functional center that everyone needs to access every day.
- Build up a general cost function based on time expended to **access and maintain center**.
- Write **average travel distance** to center as  $\bar{d}$  and assume **average speed of travel** is  $\bar{v}$ .
- Assume **isometry**: average travel distance  $\bar{d}$  will be on the length scale of the region which is  $\sim A^{1/2}$
- Average time expended per person in accessing facility is therefore

$$\bar{d}/\bar{v} = cA^{1/2}/\bar{v}$$

where  $c$  is an unimportant shape factor.

## Optimal source allocation

- Next assume facility requires regular maintenance (person-hours per day).
- Call this quantity  $\tau$ .
- If burden of maintenance is shared then average cost per person is  $\tau/P$  where  $P$  = population.
- Replace  $P$  by  $\rho_{\text{pop}}A$  where  $\rho_{\text{pop}}$  is density.
- Important assumption: uniform density.
- Total average time cost per person:

$$T = \bar{d}/\bar{v} + \tau/(\rho_{\text{pop}}A) = cA^{1/2}/\bar{v} + \tau/(\rho_{\text{pop}}A).$$

- Now Minimize with respect to  $A$  ...

## Cartograms

Diffusion-based cartograms:

☿ Idea of cartograms is to **distort areas** to more accurately represent some local density  $\rho_{\text{pop}}$  (e.g. population).

☿ Many methods put forward—typically involve some kind of physical analogy to **spreading or repulsion**.

☿ Algorithm due to Gastner and Newman (2004)<sup>[1]</sup> is based on standard diffusion:

$$\nabla^2 \rho_{\text{pop}} - \frac{\partial \rho_{\text{pop}}}{\partial t} = 0.$$

☿ Allow density to diffuse and trace the movement of individual elements and boundaries.

☿ Diffusion is constrained by boundary condition of surrounding area having density  $\bar{\rho}_{\text{pop}}$ .

## Size-density law

### Approximations:

- For a given set of source placements  $\{\vec{x}_1, \dots, \vec{x}_n\}$ , the region  $\Omega$  is divided up into Voronoi cells, one per source.
- Define  $A(\vec{x})$  as the area of the Voronoi cell containing  $\vec{x}$ .
- As per Stephan's calculation, estimate typical distance from  $\vec{x}$  to the nearest source (say  $i$ ) as

$$c_i A(\vec{x})^{1/2}$$

where  $c_i$  is a shape factor for the  $i$ th Voronoi cell.

- Approximate  $c_i$  as a constant  $c$ .

## Size-density law

### Carrying on:

- The cost function is now

$$F = c \int_{\Omega} \rho_{pop}(\vec{x}) A(\vec{x})^{1/2} d\vec{x}.$$

- We also have that the constraint that Voronoi cells divide up the overall area of  $\Omega$ :  $\sum_{i=1}^n A(\vec{x}_i) = A_{\Omega}$ .
- Sneakily turn this into an integral constraint:

$$\int_{\Omega} \frac{d\vec{x}}{A(\vec{x})} = n.$$

- Within each cell,  $A(\vec{x})$  is constant.
- So ...integral over each of the  $n$  cells equals 1.

## Size-density law

### Deriving the optimal source distribution:

- Basic idea:** Minimize the average distance from a random individual to the nearest facility. <sup>[2]</sup>
- Assume given a fixed population density  $\rho_{pop}$  defined on a spatial region  $\Omega$ .
- Formally, we want to find the locations of  $n$  sources  $\{\vec{x}_1, \dots, \vec{x}_n\}$  that minimizes the cost function

$$F(\{\vec{x}_1, \dots, \vec{x}_n\}) = \int_{\Omega} \rho_{pop}(\vec{x}) \sum_i \|\vec{x} - \vec{x}_i\| d\vec{x}.$$

- Also known as the p-median problem.
- Not easy ...in fact this one is an NP-hard problem. <sup>[2]</sup>
- Approximate solution originally due to Gusein-Zade <sup>[3]</sup>.

PoCS | @pocsvox

### Now a Lagrange multiplier story:

- By varying  $\{\vec{x}_1, \dots, \vec{x}_n\}$ , minimize

$$G(A) = c \int_{\Omega} \rho_{pop}(\vec{x}) A(\vec{x})^{1/2} d\vec{x} - \lambda \left( n - \int_{\Omega} [A(\vec{x})]^{-1} d\vec{x} \right)$$

- I Can Haz Calculus of Variations [↗](#)?
- Compute  $\delta G / \delta A$ , the functional derivative [↗](#) of the functional  $G(A)$ .
- This gives

$$\int_{\Omega} \left[ \frac{c}{2} \rho_{pop}(\vec{x}) A(\vec{x})^{-1/2} - \lambda [A(\vec{x})]^{-2} \right] d\vec{x} = 0.$$

- Setting the integrand to be zilch, we have:

$$\rho_{pop}(\vec{x}) = 2\lambda c^{-1} A(\vec{x})^{-3/2}.$$

# Size-density law

Now a Lagrange multiplier story:

Rearranging, we have

$$A(\vec{x}) = (2\lambda c^{-1})^{2/3} \rho_{\text{pop}}^{-2/3}.$$

Finally, we identify  $1/A(\vec{x})$  as  $\rho_{\text{fac}}(\vec{x})$ , an approximation of the local source density.

Substituting  $\rho_{\text{fac}} = 1/A$ , we have

$$\rho_{\text{fac}}(\vec{x}) = \left(\frac{c}{2\lambda} \rho_{\text{pop}}\right)^{2/3}.$$

Normalizing (or solving for  $\lambda$ ):

$$\rho_{\text{fac}}(\vec{x}) = n \frac{[\rho_{\text{pop}}(\vec{x})]^{2/3}}{\int_{\Omega} [\rho_{\text{pop}}(\vec{x})]^{2/3} d\vec{x}} \propto [\rho_{\text{pop}}(\vec{x})]^{2/3}.$$

# Global redistribution networks

One more thing:

- How do we supply these facilities?
- How do we best redistribute mail? People?
- How do we get beer to the pubs?
- Gastner and Newman model: cost is a function of basic maintenance and travel time:

$$C_{\text{maint}} + \gamma C_{\text{travel}}$$

Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance  $l_{ij}$  and number of legs to journey:

$$(1 - \delta)l_{ij} + \delta(\#\text{hops}).$$

When  $\delta = 1$ , only number of hops matters.

# Public versus private facilities

Beyond minimizing distances:

- "Scaling laws between population and facility densities" by Um *et al.*, Proc. Natl. Acad. Sci., 2009. [6]
- Um *et al.* find empirically and argue theoretically that the connection between facility and population density

$$\rho_{\text{fac}} \propto \rho_{\text{pop}}^{\alpha}$$

does not universally hold with  $\alpha = 2/3$ .

Two idealized limiting classes:

- For-profit, commercial facilities:  $\alpha = 1$ ;
- Pro-social, public facilities:  $\alpha = 2/3$ .

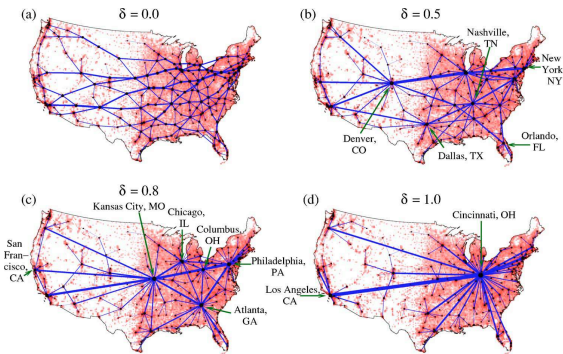

Um *et al.* investigate facility locations in the United States and South Korea.

## Public versus private facilities: the story

Either proceeding as per the Gastner-Newman-Gusein-Zade calculation or, as Um *et al.* do, observing that the cost for each cell should be the same, we have:

$$\rho_{\text{fac}}(\vec{x}) = n \frac{[\rho_{\text{pop}}(\vec{x})]^{2/(\beta+2)}}{\int_{\Omega} [\rho_{\text{pop}}(\vec{x})]^{2/(\beta+2)} d\vec{x}} \propto [\rho_{\text{pop}}(\vec{x})]^{2/(\beta+2)}$$

For  $\beta = 0$ ,  $\alpha = 1$ : commercial scaling is linear.

For  $\beta = 1$ ,  $\alpha = 2/3$ : social scaling is sublinear.

You can try this too:

## Public versus private facilities: the story

So what's going on?

- Social institutions seek to minimize distance of travel.
- Commercial institutions seek to maximize the number of visitors.
- Defns: For the  $i$ th facility and its Voronoi cell  $V_i$ , define
  - $n_i$  = population of the  $i$ th cell;
  - $\langle r_i \rangle$  = the average travel distance to the  $i$ th facility.
  - $A_i$  = area of  $i$ th cell ( $s_i$  in
- Objective function to maximize for a facility (highly constructed):

$$v_i = n_i \langle r_i \rangle^\beta \text{ with } 0 \leq \beta \leq 1.$$

Limits:

- $\beta = 0$ : purely commercial.
- $\beta = 1$ : purely social.
