## Robustness

- Many complex systems are prone to cascading catastrophic failure: **exciting!!!**
  - Blackouts
  - Disease outbreaks
  - Wildfires
  - Earthquakes
- But complex systems also show persistent **robustness** (not as exciting but important...)
- Robustness and Failure may be a power-law story...

# Robustness

- System robustness may result from
  - Evolutionary processes
  - Engineering/Design
- Idea: Explore systems optimized to perform under uncertain conditions.
- The handle: 'Highly Optimized Tolerance' (HOT) [4, 5, 6, 10]
- The catchphrase: Robust yet Fragile
- The people: Jean Carlson and John Doyle
- Great abstracts of the world #73: "There aren't any." [7]

# Robustness

## Forest fire example: [5]

- Square  $N \times N$  grid
- Sites contain a tree with probability  $\rho =$  density
- Sites are empty with probability  $1 - \rho$
- Fires start at location  $(i, j)$  according to some distribution  $P_{ij}$
- Fires spread from tree to tree (nearest neighbor only)
- Connected clusters of trees burn completely
- Empty sites block fire
- Best case scenario: Build firebreaks to maximize average # trees left intact given one spark

# Robustness

## Features of HOT systems: [5, 6]

- High performance and robustness
- Designed/evolved to handle known stochastic environmental variability
- Fragile in the face of unpredicted environmental signals
- Highly specialized, low entropy configurations
- Power-law distributions appear (of course...)

# Robustness

## Forest fire example: [5]

- Build a forest by adding one tree at a time
- Test  $D$  ways of adding one tree
- $D =$  design parameter
- Average over  $P_{ij} =$  spark probability
- $D = 1$ : random addition
- $D = N^2$ : test all possibilities

## Measure average area of forest left untouched

- $f(c) =$  distribution of fire sizes  $c (=$  cost)
- Yield  $= Y = \rho - \langle c \rangle$

# Robustness

## HOT combines things we've seen:

- Variable transformation
- Constrained optimization
- Need power law transformation between variables:  $(Y = X^{-\alpha})$
- Recall PLIPLI is bad...
- MIWO is good: Mild In, Wild Out
- $X$  has a characteristic size but  $Y$  does not

# Robustness

## Specifics:

$$P_{ij} = P_{i;a_x,b_x} P_{j;a_y,b_y}$$

where

$$P_{i;a,b} \propto e^{-[(i+a)/b]^2}$$

- In the original work,  $b_y > b_x$
- Distribution has more width in  $y$  direction.

## HOT Forests

$N = 64$

- (a)  $D = 1$
- (b)  $D = 2$
- (c)  $D = N$
- (d)  $D = N^2$

$P_{ij}$  has a Gaussian decay

- ☁ Optimized forests do well on average (robustness)
- ☁ But rare extreme events occur (fragility)

## Random Forests

$D = 1$ : Random forests = Percolation<sup>[11]</sup>

- ☁ Randomly add trees.
- ☁ Below critical density  $\rho_c$ , no fires take off.
- ☁ Above critical density  $\rho_c$ , percolating cluster of trees burns.
- ☁ Only at  $\rho_c$ , the critical density, is there a power-law distribution of tree cluster sizes.
- ☁ Forest is random and featureless.

## HOT Forests

FIG. 2. Yield vs density  $Y(\rho)$ : (a) for design parameters  $D = 1$  (dotted curve),  $2$  (dot-dashed),  $N$  (long dashed), and  $N^2$  (solid) with  $N = 64$ , and (b) for  $D = 2$  and  $N = 2, 2^2, \dots, 2^7$  running from the bottom to top curve. The results have been averaged over 100 runs. The inset to (a) illustrates corresponding loss functions  $L = \log[\langle f \rangle / (1 - \langle f \rangle)]$ , on a scale which more clearly differentiates between the curves.

## HOT forests nutshell:

- ☁ Highly structured
- ☁ Power law distribution of tree cluster sizes for  $\rho > \rho_c$
- ☁ No specialness of  $\rho_c$
- ☁ Forest states are **tolerant**
- ☁ Uncertainty is okay if well characterized
- ☁ If  $P_{ij}$  is characterized poorly, failure becomes **highly likely**

## HOT forests—Real data:

"Complexity and Robustness," Carlson & Dolye<sup>[6]</sup>

Fig. 1. Log-log (base 10) comparison of DC, WW, CF, and FF data (symbols) with 100 models (solid lines) for  $\rho = 0.0, 0.1, 0.2, \dots, 1.0$  and  $\rho = 1.1, 1.5, 0.054$ , respectively) and the SOC FF model ( $\rho = 0.15$ , dashed). Reference lines of  $\rho = 0.5, 1$  (dotted) are included. The cumulative distribution of frequencies  $P(c) = \sum_{i=1}^c f_i$  describe the area burned on the largest 2,294 fires from 1986 to 1995 on all of the U.S. Fish and Wildlife Service lands (FF), the "10,000 largest California brushfires from 1978 to 1999 (CF) (18), 150,000 web file transfers at Boston University during 1994 and 1995 (WWW) (19), and code words from DC. The size units (1,000 km<sup>2</sup> FF and CF, megabytes WWW), and bytes (DC) and the logarithmic declination of the data are chosen for visualization.

- ☁ PLR = probability-loss-resource.
- ☁ Minimize cost subject to resource (barrier) constraints:  
 $C = \sum_i p_i l_i$   
given  
 $l_i = f(r_i)$  and  $\sum r_i \leq R$ .
- ☁ DC = Data Compression.
- ☁ Horror: log. Screaming: "The base! What is the base!? You monsters!"

## HOT theory:

The abstract story, using figurative forest fires:

- Given some measure of failure size  $y_i$  and correlated resource size  $x_i$  with relationship  $y_i = x_i^{-\alpha}$ ,  $i = 1, \dots, N_{\text{sites}}$ .
- Design system to minimize  $\langle y \rangle$  subject to a constraint on the  $x_i$ .
- Minimize cost:

$$C = \sum_{i=1}^{N_{\text{sites}}} Pr(y_i) y_i$$

Subject to  $\sum_{i=1}^{N_{\text{sites}}} x_i = \text{constant}$ .

- Cost: Expected size of fire:

$$C_{\text{fire}} \propto \sum_{i=1}^{N_{\text{sites}}} p_i a_i$$

$a_i$  = area of  $i$ th site's region, and  $p_i$  = avg. prob. of fire at  $i$ th site over some time frame.

- Constraint: building and maintaining firewalls. Per unit area, and over same time frame:

$$C_{\text{firewalls}} \propto \sum_{i=1}^{N_{\text{sites}}} a_i^{1/2} a_i^{-1}$$

- We are assuming isometry.
- In  $d$  dimensions,  $1/2$  is replaced by  $(d-1)/d$

- Insert question from assignment 7 to find:

$$\Pr(a_i) \propto a_i^{-\gamma}$$

## Continuum version:

- Cost function:

$$\langle C \rangle = \int C(\vec{x}) p(\vec{x}) d\vec{x}$$

where  $C$  is some cost to be evaluated at each point in space  $\vec{x}$  (e.g.,  $V(\vec{x})^\alpha$ ), and  $p(\vec{x})$  is the probability an Ewok jabs position  $\vec{x}$  with a sharpened stick (or equivalent).

- Constraint:

$$\int R(\vec{x}) d\vec{x} = c$$

where  $c$  is a constant.

- Claim/observation is that typically <sup>[4]</sup>

$$V(\vec{x}) \sim R^{-\beta}(\vec{x})$$

- For spatial systems with barriers:  $\beta = d$ .

## SOC theory

SOC = Self-Organized Criticality

- Idea: natural dissipative systems exist at 'critical states';
- Analogy: Ising model with temperature somehow self-tuning;
- Power-law distributions of sizes and frequencies arise 'for free';
- Introduced in 1987 by Bak, Tang, and Wiesenfeld <sup>[3, 2, 8]</sup>:  
"Self-organized criticality - an explanation of 1/f noise" (PRL, 1987);
- Problem:** Critical state is a very specific point;
- Self-tuning not always possible;
- Much criticism and arguing...

## HOT versus SOC

- Both produce power laws
- Optimization versus self-tuning
- HOT systems viable over a wide range of high densities
- SOC systems have one special density
- HOT systems produce specialized structures
- SOC systems produce generic structures

# HOT theory—Summary of designed tolerance [6]

Table 1. Characteristics of SOC, HOT, and data

Property	SOC	HOT and Data
1 Internal configuration	Generic, homogeneous, self-similar	Structured, heterogeneous, self-dissimilar
2 Robustness	Generic	Robust, yet fragile
3 Density and yield	Low	High
4 Max event size	Infinitesimal	Large
5 Large event shape	Fractal	Compact
6 Mechanism for power laws	Critical internal fluctuations	Robust performance
7 Exponent $\alpha$	Small	Large
8 $\alpha$ vs. dimension $d$	$\alpha \approx (d - 1)/10$	$\alpha \approx 1/d$
9 DDOFs	Small (1)	Large ( $\infty$ )
10 Increase model resolution	No change	New structures, new sensitivities
11 Response to forcing	Homogeneous	Variable

# COLD forests

## Avoidance of large-scale failures

- Constrained Optimization with Limited Deviations [9]
- Weight cost of larges losses more strongly
- Increases average cluster size of burned trees...
- ... but reduces chances of catastrophe
- Power law distribution of fire sizes is truncated

# Cutoffs

## Observed:

- Power law distributions often have an exponential cutoff

$$P(x) \sim x^{-\gamma} e^{-x/x_c}$$

where  $x_c$  is the approximate cutoff scale.

- May be Weibull distributions:

$$P(x) \sim x^{-\gamma} e^{-\alpha x^{-\gamma+1}}$$
