## Features of HOT systems: [5, 6]

- High performance and robustness
- Designed/evolved to handle known stochastic environmental variability
- Fragile** in the face of unpredicted environmental signals
- Highly specialized, low entropy configurations
- Power-law distributions appear (of course...)

## Forest fire example: [5]

- 1 Square  $N \times N$  grid
- 2 Sites contain a tree with probability  $\rho =$  density
- 3 Sites are empty with probability  $1 - \rho$
- 4 Fires start at location  $(i, j)$  according to some distribution  $P_{ij}$
- 5 Fires spread from tree to tree (nearest neighbor only)
- 6 Connected clusters of trees burn completely
- 7 Empty sites block fire
- 8 **Best case scenario:**  
Build firebreaks to maximize average # trees left intact given one spark

## Specifics:

$$P_{ij} = P_{i;a_x,b_x} P_{j;a_y,b_y}$$

where

$$P_{i;a,b} \propto e^{-[(i+a)/b]^2}$$

In the original work,  $b_y > b_x$

Distribution has more width in  $y$  direction.

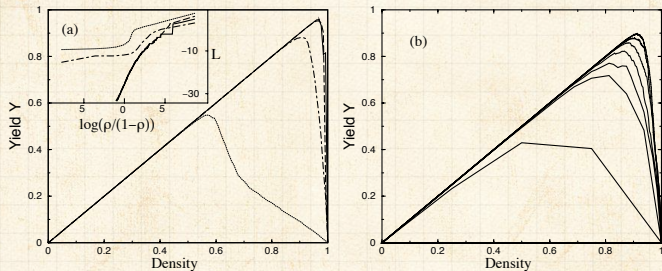

FIG. 2. Yield vs density  $Y(\rho)$ : (a) for design parameters  $D = 1$  (dotted curve), 2 (dot-dashed),  $N$  (long dashed), and  $N^2$  (solid) with  $N = 64$ , and (b) for  $D = 2$  and  $N = 2, 2^2, \dots, 2^7$  running from the bottom to top curve. The results have been averaged over 100 runs. The inset to (a) illustrates corresponding loss functions  $L = \log[\langle f \rangle / (1 - \langle f \rangle)]$ , on a scale which more clearly differentiates between the curves.

$D = 1$ : Random forests = Percolation [11]

 Randomly add trees.

-  Below critical density  $\rho_c$ , no fires take off.
-  Above critical density  $\rho_c$ , percolating cluster of trees burns.
-  Only at  $\rho_c$ , the critical density, is there a power-law distribution of tree cluster sizes.
-  Forest is random and featureless.

## “Complexity and Robustness,” Carlson & Dolye [6]

Fig. 1. Log-log (base 10) comparison of DC, WWW, CF, and FF data (symbols) with PLR models (solid lines) (for  $\beta = 0, 0.9, 0.9, 1.85$ , or  $\alpha = 1/\beta = \infty, 1.1, 1.1, 0.054$ , respectively) and the SOC FF model ( $\alpha = 0.15$ , dashed). Reference lines of  $\alpha = 0.5, 1$  (dashed) are included. The cumulative distributions of frequencies  $\mathcal{P}(l \geq l)$  vs.  $l_i$  describe the areas burned in the largest 4,284 fires from 1986 to 1995 on all of the U.S. Fish and Wildlife Service Lands (FF) (17), the >10,000 largest California brushfires from 1878 to 1999 (CF) (18), 130,000 web file transfers at Boston University during 1994 and 1995 (WWW) (19), and code words from DC. The size units [1,000 km<sup>2</sup> (FF and CF), megabytes (WWW), and bytes (DC)] and the logarithmic decimation of the data are chosen for visualization.

PLR = probability-loss-resource.

Minimize cost subject to resource (barrier) constraints:

$$C = \sum_i p_i l_i$$

given

$$l_i = f(r_i) \text{ and } \sum r_i \leq R.$$

DC = Data Compression.

Horror: log. Screaming: “The base! What is the base!? You monsters!”

# HOT theory—Summary of designed tolerance <sup>[6]</sup>

**Table 1. Characteristics of SOC, HOT, and data**

	Property	SOC	HOT and Data
1	Internal configuration	Generic, homogeneous, self-similar	Structured, heterogeneous, self-dissimilar
2	Robustness	Generic	Robust, yet fragile
3	Density and yield	Low	High
4	Max event size	Infinitesimal	Large
5	Large event shape	Fractal	Compact
6	Mechanism for power laws	Critical internal fluctuations	Robust performance
7	Exponent $\alpha$	Small	Large
8	$\alpha$ vs. dimension $d$	$\alpha \approx (d - 1)/10$	$\alpha \approx 1/d$
9	DDOFs	Small (1)	Large ( $\infty$ )
10	Increase model resolution	No change	New structures, new sensitivities
11	Response to forcing	Homogeneous	Variable

## Observed:

- Power law distributions often have an exponential cutoff

$$P(x) \sim x^{-\gamma} e^{-x/x_c}$$

where  $x_c$  is the approximate cutoff scale.

- May be Weibull distributions:

$$P(x) \sim x^{-\gamma} e^{-ax^{-\gamma+1}}$$
