Size-density law Cartograms A reasonable derivation Global redistribution Public versus Private

How do we distribute sources?

Focus on 2-d (results generalize to higher dimensions).

Sources hospitals, post offices, pubs, ...

Key problem: How do we cope with uneven population densities?

Obvious: if density is uniform then sources are best distributed uniformly.

Which lattice is optimal?

Q2. Given population density is uneven, what do we do?

We'll follow work by Stephan (1977, 1984)
Gastner and Newman (2006) , Um et al. (2009) and work cited by them.

Size-density law Cartograms A reasonable derivation

Global redistribution Public versus Private

Size-density law:

 $ho_{
m fac} \propto
ho_{
m pop}^{2/3}$

Why

Again: Different story to branching networks where there was either one source or one sink.

Now sources & sinks are distributed throughout region.

Distributed Sources

Size-density law

A reasonable derivation Global redistribution Public versus Private

Consider a region of area A and population P with a single functional center that everyone needs to access every day.

Build up a general cost function based on time expended to access and maintain center.

Write average travel distance to center as \bar{d} and assume average speed of travel is \bar{v} .

Assume isometry: average travel distance \bar{d} will be on the length scale of the region which is $\sim A^{1/2}$

Average time expended per person in accessing facility is therefore

$$\bar{d}/\bar{v} = cA^{1/2}/\bar{v}$$

where c is an unimportant shape factor.

Diffusion-based cartograms:

- Idea of cartograms is to distort areas to more accurately represent some local density ρ_{pop} (e.g. population).
- Many methods put forward—typically involve, some kind of physical analogy to spreading or repulsion.
- Algorithm due to Gastner and Newman (2004) is based on standard diffusion:

$$\nabla^2 \rho_{\mathsf{pop}} - \frac{\partial \rho_{\mathsf{pop}}}{\partial t} = 0$$

- Allow density to diffuse and trace the movement of individual elements and boundaries.
- Diffusion is constrained by boundary condition of surrounding area having density ρ_{pop} .

Deriving the optimal source distribution:

Basicidea: Minimize the average distance from a random individual to the nearest facility.

Assume given a fixed population density $\rho_{\rm pop}$ defined on a spatial region $\Omega.$

Formally, we want to find the locations of n sources $\{\vec{x}_1, \dots, \vec{x}_n\}$ that minimizes the cost-function

$$F(\{\vec{x}_1,\ldots,\vec{x}_n\}) = \int_{\Omega} \rho_{\mathrm{pop}}(\vec{x}) \min_{\vec{x}} ||\vec{x} - \vec{x}_{\vec{x}}|| \mathrm{d}\vec{x}$$

Deriving the optimal source distribution:

- Basic idea: Minimize the average distance from a random individual to the nearest facility. [2]
- Assume given a fixed population density ρ_{pop} defined on a spatial region $\Omega.$
- Formally, we want to find the locations of n sources $\{\vec{x}_1,\dots,\vec{x}_n\}$ that minimizes the cost function

$$F(\{\vec{x}_1,\dots,\vec{x}_n\}) = \int_{\Omega} \frac{\rho_{\mathsf{pop}}(\vec{x}) \min_i ||\vec{x}-\vec{x}_i|| \mathrm{d}\vec{x} \,.$$

Also known as the p-median problem.

Not easy ...

Approximate solution originally due to Gusein-Zade

How do we get beer to the pubs?

Gastner and Newman model: cost is a function of basic maintenance and travel time:

 $C_{\mathsf{maint}} + \gamma C_{\mathsf{travel}}.$

Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance ℓ_{ij} and number of legs to journey:

 $(1-\delta)\ell_{ij} + \delta(\#\mathsf{hops})$

When $\delta = 1$, only number of hops matters.

Either proceeding as per the Gastner-Newman-Gusein-Zade calculation or, as Um et al. do, observing that the cost for each cell should be the same, we have:

$$\label{eq:rhofac} \begin{split} & \rho_{\rm fac}(\vec{x}) = n \frac{[\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)}}{\int_{\Omega} [\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)} \mathrm{d}\vec{x}} \propto [\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)}. \end{split}$$

$$\rho_{\rm fac}(\vec{x}) = n \frac{[\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)}}{\int_{\Omega} [\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)} {\rm d}\vec{x}} \propto [\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)}.$$

 \Longrightarrow For $\beta = 0$, $\alpha = 1$: commercial scaling is linear.

 \Rightarrow For $\beta = 1$, $\alpha = 2/3$: social scaling is sublinear.
