$$P = c M^\alpha$$

Prefactor c depends on **body plan** and **body temperature**:

Birds	39–41 °C
Eutherian Mammals	36–38 °C
Marsupials	34–36 °C
Monotremes	30–31 °C

The prevailing belief of the Church of Quarterology:

Most obvious concern:

$$3/4 - 2/3 = 1/12$$

- ☸ An exponent higher than $2/3$ points suggests a fundamental inefficiency in biology.
- ☸ Organisms must somehow be running 'hotter' than they need to balance heat loss.

CocoNuTS

Metabolism and Truthicide

11 of 126

What one might expect:

$\alpha = 2/3$ because ...

- ☸ Dimensional analysis suggests an energy balance surface law:

$$P \propto S \propto V^{2/3} \propto M^{2/3}$$

- ☸ Assumes isometric scaling (not quite the spherical cow).

- ☸ **Lognormal fluctuations:** Gaussian fluctuations in $\log_{10} P$ around $\log_{10} cM^\alpha$.

- ☸ Stefan-Boltzmann law for radiated energy:

$$\frac{dE}{dt} = \sigma \epsilon S T^4 \propto S$$

Related putative scalings:

Wait! There's more!:

- ☸ number of capillaries $\propto M^{3/4}$
- ☸ time to reproductive maturity $\propto M^{1/4}$
- ☸ heart rate $\propto M^{-1/4}$
- ☸ cross-sectional area of aorta $\propto M^{3/4}$
- ☸ population density $\propto M^{-3/4}$

The great 'law' of heartbeats:

Assuming:

- Average lifespan $\propto M^\beta$
- Average heart rate $\propto M^{-\beta}$
- Irrelevant but perhaps $\beta = 1/4$.

Then:

$$\begin{aligned} \text{Average number of heart beats in a lifespan} \\ \approx (\text{Average lifespan}) \times (\text{Average heart rate}) \\ \propto M^{\beta-\beta} \\ \propto M^0 \end{aligned}$$

Number of heartbeats per life time is independent of organism size!

≈ 1.5 billion ...

"A general scaling law reveals why the largest animals are not the fastest" [Hirt et al., Nature Ecology & Evolution, 1, 1116, 2017. \[23\]](#)

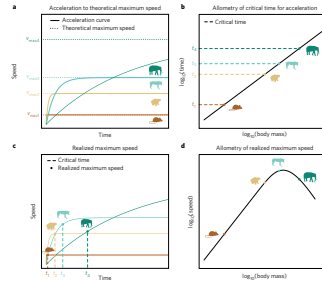

Figure 1 Concept of time-dependent and mass-dependent realized maximum speed of animals. a. Acceleration of animals follows a saturation curve (solid lines) approaching the theoretical maximum speed (dotted lines) depending on body mass (color code). b. The time available for acceleration increases with body mass following a power law $\propto M^d$. This critical time governs the realized maximum speed (c), leading a hump-shaped increase of maximum speed with body mass (d).

Theoretical story:

Figure 4 Predicting the maximum speed of extinct species with the time-dependent model. The model prediction (grey line) is fitted to data of extant species (grey circles) and extended to higher body masses. Speed data for dinosaurs (green triangles) come from detailed morphological model calculations (Tables 1) and were not used to obtain model parameters.

Maximum speed increases with size: $v_{max} = aM^b$

Takes a while to get going: $v(t) = v_{max}(1 - e^{-kt})$

$k \sim F_{max}/M \sim cM^{d-1}$
Literature: $0.75 \lesssim d \lesssim 0.94$

Acceleration time = depletion time for anaerobic energy: $\tau \sim fM^g$
Literature: $0.76 \lesssim g \lesssim 1.27$

$v_{max} = aM^b (1 - e^{-hM^i})$

$i = d - 1 + g$ and $h = cf$

Literature search for for maximum speeds of running, flying and swimming animals.

Search terms: "maximum speed", "escape speed" and "sprint speed".

Linear regression

Important:

Ordinary Least Squares (OLS) Linear regression is only appropriate for analyzing a dataset $\{(x_i, y_i)\}$ when we know the x_i are measured without error.

Here we assume that measurements of mass M have less error than measurements of metabolic rate B .

Linear regression assumes Gaussian errors.

For Standardized Major Axis Linear Regression:

$$\text{slope}_{\text{SMA}} = \frac{\text{standard deviation of } y \text{ data}}{\text{standard deviation of } x \text{ data}}$$

Very simple!

Minimization of sum of areas of triangles induced by vertical and horizontal residuals with best fit line.

The only linear regression that is *Scale invariant*.

Attributed to Nobel Laureate economist Paul Samuelson^[43] but discovered independently by others.

Death by fractions

Measuring exponents

River networks

Earlier theories

Geometric argument

Conclusion

References

32 of 126

Measuring exponents

Relationship to ordinary least squares regression is simple:

$$\begin{aligned} \text{slope}_{\text{SMA}} &= r^{-1} \times \text{slope}_{\text{OLS } y \text{ on } x} \\ &= r \times \text{slope}_{\text{OLS } x \text{ on } y} \end{aligned}$$

where r = standard correlation coefficient:

$$r = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}}$$

🌀 Groovy upshot: If (1) a paper uses OLS regression when RMA would be appropriate, and (2) r is reported, we can figure out the RMA slope. [41, 29]

- 🌀 Disparity between slopes for y on x and x on y regressions is a factor of r^2 (r^{-2})
- 🌀 (Rayner uses ρ for r .)
- 🌀 Here: $r^2 = .435^2 = 0.189$, and $r^{-2} = .435^{-2} = 2.29^2 = 5.285$.
- 🌀 See also: LaBarbera [29] (who resigned ...)

Analysis of residuals

We use the spiffing Spearman Rank-Order Correlation Coefficient

Basic idea:

Given $\{(x_i, y_i)\}$, rank the $\{x_i\}$ and $\{y_i\}$ separately from smallest to largest. Call these ranks R_i and S_i .

Now calculate correlation coefficient for ranks, r_s :

$$r_s = \frac{\sum_{i=1}^n (R_i - \bar{R})(S_i - \bar{S})}{\sqrt{\sum_{i=1}^n (R_i - \bar{R})^2} \sqrt{\sum_{i=1}^n (S_i - \bar{S})^2}}$$

Perfect correlation: x_i 's and y_i 's both increase monotonically.

Analysis of residuals

We assume all rank orderings are equally likely:

r_s is distributed according to a Student's t -distribution with $N - 2$ degrees of freedom.

Excellent feature: Non-parametric—real distribution of x 's and y 's doesn't matter.

Bonus: works for non-linear monotonic relationships as well.

See Numerical Recipes in C/Fortran which contains many good things.

Analysis of residuals

- Presume an exponent of your choice: 2/3 or 3/4.
- Fit the prefactor ($\log_{10} c$) and then examine the residuals:

$$r_i = \log_{10} B_i - (\alpha' \log_{10} M_i - \log_{10} c).$$

- H_0 : residuals are uncorrelated
 H_1 : residuals are correlated.
- Measure the correlations in the residuals and compute a p -value.

Not so fast ...

Actually, model shows:

- $P \propto M^{3/4}$ does not follow for pulsatile flow
- networks are not necessarily fractal.

Do find:

- Murray's cube law (1927) for outer branches: [37]

$$r_0^3 = r_1^3 + r_2^3$$

- Impedance is distributed evenly.
- Can still assume networks are fractal.

Connecting network structure to α

- Ratios of network parameters:

$$R_n = \frac{n_{k+1}}{n_k}, R_\ell = \frac{\ell_{k+1}}{\ell_k}, R_r = \frac{r_{k+1}}{r_k}$$

- Number of capillaries $\propto P \propto M^\alpha$.

$$\Rightarrow \alpha = -\frac{\ln R_n}{\ln R_r^2 R_\ell}$$

(also problematic due to prefactor issues)

Obliviously soldiering on, we could assert:

- area-preservingness: $R_r = R_n^{-1/2} \Rightarrow \alpha = 3/4$
- space-fillingness: $R_\ell = R_n^{-1/3}$

Impedance measures:

- Poiseuille flow (outer branches):

$$Z = \frac{8\mu}{\pi} \sum_{k=0}^N \frac{\ell_k}{r_k^4 N_k}$$

- Pulsatile flow (main branches):

$$Z \propto \sum_{k=0}^N \frac{h_k^{1/2}}{r_k^{5/2} N_k}$$

- Wheel out Lagrange multipliers ...
- Poiseuille gives $P \propto M^1$ with a logarithmic correction.
- Pulsatile calculation explodes into flames.

Yah:

Figure 1 | Curvature in metabolic scaling. a. Linear (red) and quadratic (blue) fits (not including temperature) of $\log_{10}B$ versus $\log_{10}M$. The orca (green square) and Asian elephant (red square at larger mass) are not included in the fit, but are predicted well. Differences in the quality of fit are best seen in terms of the conditional mean of the error, estimated by the loess (locally-weighted scatterplot smoothing) fit of the residuals (Supplementary Information). See Table 1 for the values of the coefficients obtained from the fit. b. Slope of the quadratic fit (including temperature) with pointwise 95% confidence intervals (black). The slope of the power law fit (red) and models with fixed 2/3 and 3/4 exponents (black) are included for comparison. This panel suggests that exponents estimated by assuming a power law will be highly sensitive to the mass range of the data set used, as shown in Fig. 2.

Minimal network volume:

For $0 \leq \epsilon < 1/2$, approximate network volume by integral over region:

$$\min V_{\text{net}} \propto \int_{\Omega_{d,D}(V)} \rho \|\vec{x}\|^{1-2\epsilon} d\vec{x}$$

Insert question, assignment 4 <2>

$$\propto \rho V^{1+\gamma_{\text{max}}(1-2\epsilon)} \text{ where } \gamma_{\text{max}} = \max_i \gamma_i.$$

For $\epsilon > 1/2$, find simply that

$$\min V_{\text{net}} \propto \rho V$$

- So if supply lines can taper fast enough and without limit, minimum network volume can be made negligible.

CocoNuTS

- Metabolism and Truticidae
- Death by fractions
- Measuring exponents
- River networks
- Earlier theories
- Geometric argument
- Conclusion
- References

For $0 \leq \epsilon < 1/2$:

$\min V_{\text{net}} \propto \rho V^{1+\gamma_{\text{max}}(1-2\epsilon)}$

If scaling is **isometric**, we have $\gamma_{\text{max}} = 1/d$:

$\min V_{\text{net/iso}} \propto \rho V^{1+(1-2\epsilon)/d}$

If scaling is **allometric**, we have $\gamma_{\text{max}} = \gamma_{\text{allo}} > 1/d$:
and

$\min V_{\text{net/allo}} \propto \rho V^{1+(1-2\epsilon)\gamma_{\text{allo}}}$

Isometrically growing volumes **require less network volume** than allometrically growing volumes:

$\frac{\min V_{\text{net/iso}}}{\min V_{\text{net/allo}}} \rightarrow 0 \text{ as } V \rightarrow \infty$

CocoNuTS

Blood networks

Velocity at capillaries and aorta approximately constant across body size [51]: $\epsilon = 0$.

Material costly \Rightarrow expect lower optimal bound of $V_{\text{net}} \propto \rho V^{(d+1)/d}$ to be followed closely.

For cardiovascular networks, $d = D = 3$.

Blood volume scales linearly with body volume [47], $V_{\text{net}} \propto V$.

Sink density must \therefore decrease as volume increases:

$\rho \propto V^{-1/d}$.

Density of suppliable sinks **decreases** with organism size.

CocoNuTS

- Metabolism and Truthicide
- Death by fractions
- Measuring exponents
- River networks
- Earlier theories
- Geometric argument
- Conclusion
- References

For $\epsilon > 1/2$:

$\min V_{\text{net}} \propto \rho V$

Network volume scaling is now independent of overall shape scaling.

Limits to scaling

Can argue that ϵ must effectively be 0 for real networks over large enough scales.

Limit to how fast material can move, and how small material packages can be.

e.g., blood velocity and blood cell size.

CocoNuTS

- Metabolism and Truthicide
- Death by fractions

Hack's law

- Volume of water in river network can be calculated by adding up basin areas
- Flows sum in such a way that

$$V_{\text{net}} = \sum_{\text{all pixels } i} a_{\text{pixel } i}$$

- Hack's law again:

$$\ell \sim a^h$$

- Can argue

$$V_{\text{net}} \propto V_{\text{basin}}^{1+h} = a_{\text{basin}}^{1+h}$$

where h is Hack's exponent.

- ∴ minimal volume calculations gives

$$h = 1/2$$

River networks

- View river networks as collection networks.
- Many sources and one sink.
- ϵ ?
- Assume ρ is constant over time and $\epsilon = 0$:

$$V_{\text{net}} \propto \rho V^{(d+1)/d} = \text{constant} \times V^{3/2}$$

- Network volume grows faster than basin 'volume' (really area).
- It's all okay: Landscapes are $d=2$ surfaces living in $D=3$ dimensions.
- Streams can grow not just in width but in depth ...
- If $\epsilon > 0$, V_{net} will grow more slowly but 3/2 appears to be confirmed from real data.

"Critical truths about power laws" [48] Stumpf and Porter, Science, 2012

How good is your power law? The chart reflects the level of statistical support—as measured in (26, 21)—and our opinion about the mechanistic sophistication underlying hypothetical generative models for various reported power laws. Some relationships are identified by name; the others reflect the general characteristics of a wide range of reported power laws. Allometric scaling stands out from the other power laws reported for complex systems.

- 🔗 Call generalization of Central Limit Theorem, stable distributions. Also: PLIPL0 action.
- 🔗 Summary: Wow.

Some people understand it's truly a disaster: ↗

Peter Sheridan Dodds, Theoretical Biology's Buzzkill

By Mark Changizi | February 9th 2010 03:24 PM | 1 comment | Print | E-mail | Track Comments

Share / Save | Facebook | Twitter | Like

There is an apocryphal story about a graduate mathematics student at the University of Virginia studying the properties of certain mathematical objects. In his fifth year some killjoy bastard elsewhere published a paper proving that there are no such mathematical objects. He dropped out of the program, and I never did hear where he is today. He's probably making my cappuccino right now.

This week, a professor named Peter Sheridan Dodds published a new paper in *Physical Review Letters* further fleshing out a theory concerning why a $2/3$ power law may apply for metabolic rate. The $2/3$ law says that metabolic rate in animals rises as the $2/3$ power of body mass. It was in a 2001 *Journal of Theoretical Biology* paper that he first argued that perhaps a $2/3$ law applies, and that paper—along with others such as the one that just appeared—is what has put him in the Killjoy Hall of Fame. The University of Virginia's killjoy was a mere amateur.

Conclusion

- 🔗 Supply network story consistent with dimensional analysis.
- 🔗 Isometrically growing regions can be more efficiently supplied than allometrically growing ones.
- 🔗 Ambient and region dimensions matter ($D = d$ versus $D > d$).
- 🔗 Deviations from optimal scaling suggest inefficiency (e.g., gravity for organisms, geological boundaries).
- 🔗 Actual details of branching networks not that important.
- 🔗 Exact nature of self-similarity varies.
- 🔗 $2/3$ -scaling lives on, largely in hiding.
- 🔗 $3/4$ -scaling? Jury ruled a mistrial.
- 🔗 The truth will out. Maybe.
