Piracy on the high χ 's:

"Dynamic Reorganization of River Basins"

Willett et al.,

Science Magazine, **343**, 1248765, 2014. [21]

$$\frac{\partial z(x, t)}{\partial t} = U - KA^m \left| \frac{\partial z(x, t)}{\partial x} \right|^n$$

$$z(x) = z_b + \left(\frac{U}{KA_0^m} \right)^{1/n} \chi$$

$$\chi = \int_{x_b}^x \left(\frac{A_0}{A(x')} \right)^{m/n} dx'$$

Piracy on the high χ 's:

Can Horton and Tokunaga be happy?

Horton and Tokunaga seem different:

- In terms of network architecture, Horton's laws appear to contain less detailed information than Tokunaga's law.
- Oddly, Horton's laws have **four** parameters and Tokunaga has **two** parameters.
- $R_n, R_a, R_\ell,$ and R_s **versus** T_1 and R_T . One simple redundancy: $R_\ell = R_s$.
Insert question from assignment 1 [↗](#)
- To make a connection, clearest approach is to start with Tokunaga's law ...
- Known result: Tokunaga \rightarrow Horton ^[18, 19, 20, 9, 2]

More with the happy-making thing

Putting things together:

$$n_\omega = \underbrace{2n_{\omega+1}}_{\text{generation}} + \sum_{\omega'=\omega+1}^{\Omega} \underbrace{T_{\omega'-\omega}n_{\omega'}}_{\text{absorption}}$$

- Use Tokunaga's law and manipulate expression to find Horton's law for stream numbers follows and hence obtain R_n .
- Insert question from assignment 1 [↗](#)

Solution:

$$R_n = \frac{(2 + R_T + T_1) \pm \sqrt{(2 + R_T + T_1)^2 - 8R_T}}{2}$$

(The larger value is the one we want.)

Let us make them happy

We need one more ingredient:

Space-fillingness

- A network is **space-filling** if the average distance between adjacent streams is roughly constant.
- Reasonable for river and cardiovascular networks
- For river networks:
Drainage density ρ_{dd} = inverse of typical distance between channels in a landscape.
- In terms of basin characteristics:

$$\rho_{dd} \approx \frac{\sum \text{stream segment lengths}}{\text{basin area}} = \frac{\sum_{\omega=1}^{\Omega} n_\omega \bar{s}_\omega}{a_\Omega}$$

11 of 87

Finding other Horton ratios

Connect Tokunaga to R_s

- Now use uniform drainage density ρ_{dd} .
- Assume side streams are roughly separated by distance $1/\rho_{dd}$.
- For an order ω **stream segment**, expected length is

$$\bar{s}_\omega \approx \rho_{dd}^{-1} \left(1 + \sum_{k=1}^{\omega-1} T_k \right)$$

- Substitute in Tokunaga's law $T_k = T_1 R_T^{k-1}$:

$$\bar{s}_\omega \approx \rho_{dd}^{-1} \left(1 + T_1 \sum_{k=1}^{\omega-1} R_T^{k-1} \right) \propto R_T^\omega$$

More with the happy-making thing

Start with Tokunaga's law: $T_k = T_1 R_T^{k-1}$

- Start looking for Horton's stream number law:
 $n_\omega/n_{\omega+1} = R_n$.
- Estimate n_ω , the number of streams of order ω in terms of other $n_{\omega'}, \omega' > \omega$.
- Observe that each stream of order ω terminates by either:

- Running into another stream of order ω and generating a stream of order $\omega + 1$...
▶ $2n_{\omega+1}$ streams of order ω do this
- Running into and being absorbed by a stream of higher order $\omega' > \omega$...
▶ $n_{\omega'} T_{\omega'-\omega}$ streams of order ω do this

Horton and Tokunaga are happy

Altogether then:

$$\Rightarrow \bar{s}_\omega / \bar{s}_{\omega-1} = R_T \Rightarrow R_s = R_T$$

- Recall $R_\ell = R_s$ so

$$R_\ell = R_s = R_T$$

- And from before:

$$R_n = \frac{(2 + R_T + T_1) + \sqrt{(2 + R_T + T_1)^2 - 8R_T}}{2}$$

Horton and Tokunaga are happy

Some observations:

- R_n and R_ℓ depend on T_1 and R_T .
- Seems that R_a must as well ...
- Suggests Horton's laws must contain some redundancy
- We'll in fact see that $R_a = R_n$.
- Also: Both Tokunaga's law and Horton's laws can be generalized to relationships between non-trivial statistical distributions. [3, 4]

Horton and Tokunaga are friends

...and in detail:

- Must retain same drainage density.
- Add an extra $(R_\ell - 1)$ first order streams for each original tributary.
- Since by definition, an order $\omega + 1$ stream segment has T_ω order 1 side streams, we have:

$$T_k = (R_\ell - 1) \left(1 + \sum_{i=1}^{k-1} T_i \right)$$

- For large ω , Tokunaga's law is the solution—let's check ...

Horton and Tokunaga are happy

The other way round

- Note: We can invert the expressions for R_n and R_ℓ to find Tokunaga's parameters in terms of Horton's parameters.

$$R_T = R_\ell,$$

$$T_1 = R_n - R_\ell - 2 + 2R_\ell/R_n.$$

- Suggests we should be able to argue that Horton's laws imply Tokunaga's laws (if drainage density is uniform) ...

Horton and Tokunaga are friends

Just checking:

- Substitute Tokunaga's law $T_i = T_1 R_T^{i-1} = T_1 R_\ell^{i-1}$ into

$$T_k = (R_\ell - 1) \left(1 + \sum_{i=1}^{k-1} T_i \right)$$

$$T_k = (R_\ell - 1) \left(1 + \sum_{i=1}^{k-1} T_1 R_\ell^{i-1} \right)$$

$$= (R_\ell - 1) \left(1 + T_1 \frac{R_\ell^k - 1}{R_\ell - 1} \right)$$

$$\simeq (R_\ell - 1) T_1 \frac{R_\ell^{k-1}}{R_\ell - 1} = T_1 R_\ell^{k-1} \quad \dots \text{yep.}$$

Horton and Tokunaga are friends

From Horton to Tokunaga [2]

- Assume Horton's laws hold for number and length
- Start with picture showing an order ω stream and order $\omega - 1$ generating and side streams.
- Scale up by a factor of R_ℓ , orders increment to $\omega + 1$ and ω .
- Maintain drainage density by adding new order $\omega - 1$ streams

Reducing Horton's laws:

Rough first effort to show $R_n \equiv R_a$:

$a_\Omega \propto$ sum of all stream segment lengths in a order Ω basin (assuming uniform drainage density)

So:

$$a_\Omega \simeq \sum_{\omega=1}^{\Omega} n_\omega \bar{s}_\omega / \rho_{dd}$$

$$\propto \sum_{\omega=1}^{\Omega} \underbrace{R_n^{\Omega-\omega}}_{n_\omega} \cdot \underbrace{1}_{\bar{s}_1} \cdot \underbrace{\bar{s}_1}_{\bar{s}_\omega} \cdot R_s^{\omega-1}$$

$$= \frac{R_n^\Omega}{R_s} \bar{s}_1 \sum_{\omega=1}^{\Omega} \left(\frac{R_s}{R_n} \right)^\omega$$

Reducing Horton's laws:

Continued ...

$$a_\Omega \propto \frac{R_n^\Omega}{R_s} \bar{s}_1 \sum_{\omega=1}^{\Omega} \left(\frac{R_s}{R_n} \right)^\omega$$

$$= \frac{R_n^\Omega}{R_s} \bar{s}_1 \frac{R_s}{R_n} \frac{1 - (R_s/R_n)^\Omega}{1 - (R_s/R_n)}$$

$$\sim R_n^{\Omega-1} \bar{s}_1 \frac{1}{1 - (R_s/R_n)} \text{ as } \Omega \nearrow$$

So, a_Ω is growing like R_n^Ω and therefore:

$$R_n \equiv R_a$$

Equipartitioning:

Intriguing division of area:

- Observe: Combined area of basins of order ω independent of ω .
- Not obvious: basins of low orders not necessarily contained in basins on higher orders.
- Story:

$$R_n \equiv R_a \Rightarrow n_\omega \bar{a}_\omega = \text{const}$$

- Reason:

$$n_\omega \propto (R_n)^{-\omega}$$

$$\bar{a}_\omega \propto (R_a)^\omega \propto n_\omega^{-1}$$

Scaling laws

The story so far:

- Natural branching networks are **hierarchical, self-similar** structures
- Hierarchy is **mixed**
- Tokunaga's law describes detailed architecture:
 $T_k = T_1 R_T^{k-1}$.
- We have connected Tokunaga's and Horton's laws
- Only two Horton laws are independent ($R_n = R_a$)
- Only **two** parameters are **independent**:
 $(T_1, R_T) \Leftrightarrow (R_n, R_s)$

Scaling laws

A little further ...

- Ignore stream ordering for the moment
- Pick a random location on a branching network p .
- Each point p is associated with a basin and a longest stream length
- Q:** What is probability that the p 's drainage basin has area a ? $P(a) \propto a^{-\tau}$ for large a
- Q:** What is probability that the longest stream from p has length ℓ ? $P(\ell) \propto \ell^{-\gamma}$ for large ℓ
- Roughly observed: $1.3 \lesssim \tau \lesssim 1.5$ and $1.7 \lesssim \gamma \lesssim 2.0$

Scaling laws

Probability distributions with power-law decays

- We see them everywhere:
 - Earthquake magnitudes (Gutenberg-Richter law)
 - City sizes (Zipf's law)
 - Word frequency (Zipf's law) [22]
 - Wealth (maybe not—at least heavy tailed)
 - Statistical mechanics (phase transitions) [5]
- A big part of the story of complex systems
- Arise from **mechanisms**: growth, randomness, optimization, ...
- Our task is always to illuminate the mechanism ...

Scaling laws

Hack's law: [6]

$$\ell \propto a^h$$

Typically observed that $0.5 \lesssim h \lesssim 0.7$.

Use Horton laws to connect h to Horton ratios:

$$\bar{\ell}_\omega \propto R_s^\omega \text{ and } \bar{a}_\omega \propto R_n^\omega$$

Observe:

$$\begin{aligned} \bar{\ell}_\omega &\propto e^{\omega \ln R_s} \propto (e^{\omega \ln R_n})^{\ln R_s / \ln R_n} \\ &\propto (R_n^\omega)^{\ln R_s / \ln R_n} \propto \bar{a}_\omega^{\ln R_s / \ln R_n} \Rightarrow h = \ln R_s / \ln R_n \end{aligned}$$

Scaling laws

Finding γ :

Therefore:

$$P_{>}(\bar{\ell}_\omega) \propto e^{-\omega \ln(R_n/R_s)} = (e^{\omega \ln R_s})^{-\ln(R_n/R_s)/\ln(R_s)}$$

$$\propto \bar{\ell}_\omega^{-\ln(R_n/R_s)/\ln R_s}$$

$$= \bar{\ell}_\omega^{-(\ln R_n - \ln R_s)/\ln R_s}$$

$$= \bar{\ell}_\omega^{-\ln R_n / \ln R_s + 1}$$

$$= \bar{\ell}_\omega^{-\gamma + 1}$$

We mentioned there were a good number of 'laws': [2]

Relation:	Name or description:
$T_k = T_1 (R_T)^{k-1}$	Tokunaga's law
$\ell \sim L^d$	self-affinity of single channels
$n_\omega / n_{\omega+1} = R_n$	Horton's law of stream numbers
$\ell_{\omega+1} / \ell_\omega = R_\ell$	Horton's law of main stream lengths
$\bar{a}_{\omega+1} / \bar{a}_\omega = R_a$	Horton's law of basin areas
$\bar{s}_{\omega+1} / \bar{s}_\omega = R_s$	Horton's law of stream segment lengths
$L_\perp \sim L^H$	scaling of basin widths
$P(a) \sim a^{-\tau}$	probability of basin areas
$P(\ell) \sim \ell^{-\gamma}$	probability of stream lengths
$\ell \sim a^h$	Hack's law
$a \sim L^D$	scaling of basin areas
$\Lambda \sim a^\beta$	Langbein's law
$\lambda \sim L^\varphi$	variation of Langbein's law

Connecting exponents

Only 3 parameters are independent:
e.g., take d , R_n , and R_s

relation:	scaling relation/parameter: [2]
$\ell \sim L^d$	d
$T_k = T_1 (R_T)^{k-1}$	$T_1 = R_n - R_s - 2 + 2R_s/R_n$ $R_T = R_s$
$n_\omega/n_{\omega+1} = R_n$	R_n
$\bar{a}_{\omega+1}/\bar{a}_\omega = R_a$	$R_a = R_n$
$\bar{\ell}_{\omega+1}/\bar{\ell}_\omega = R_\ell$	$R_\ell = R_s$
$\ell \sim a^h$	$h = \ln R_s / \ln R_n$
$a \sim L^D$	$D = d/h$
$L_\perp \sim L^H$	$H = d/h - 1$
$P(a) \sim a^{-\tau}$	$\tau = 2 - h$
$P(\ell) \sim \ell^{-\gamma}$	$\gamma = 1/h$
$\Lambda \sim a^\beta$	$\beta = 1 + h$
$\lambda \sim L^\varphi$	$\varphi = d$

Scheidegger's model

Prob for first return of a random walk in (1+1) dimensions (from CSYS/MATH 300):

$$P(n) \sim \frac{1}{2\sqrt{\pi}} n^{-3/2}$$

and so $P(\ell) \propto \ell^{-3/2}$.

Typical area for a walk of length n is $\propto n^{3/2}$:

$$\ell \propto a^{2/3}$$

Find $\tau = 4/3$, $h = 2/3$, $\gamma = 3/2$, $d = 1$.

Note $\tau = 2 - h$ and $\gamma = 1/h$.

R_n and R_ℓ have not been derived analytically.

Equipartitioning

What about

$$P(a) \sim a^{-\tau} \quad ?$$

Since $\tau > 1$, suggests no equipartitioning:

$$aP(a) \sim a^{-\tau+1} \neq \text{const}$$

- $P(a)$ overcounts basins within basins ...
- while stream ordering separates basins ...

Branching networks II Key Points:

- Landscapes $h(\vec{x})$ evolve such that energy dissipation $\dot{\epsilon}$ is minimized, where $\dot{\epsilon} \propto \int d\vec{r} (\text{flux}) \times (\text{force}) \sim \sum_i a_i \nabla h_i \sim \sum_i a_i^\gamma$
- Landscapes obtained numerically give exponents near that of real networks.
- But:** numerical method used matters.
- And:** Maritan et al. find basic universality classes are that of Scheidegger, self-similar, and a third kind of random network [8]
- Horton's laws and Tokunaga law all fit together.
- For 2-d networks, these laws are 'planform' laws and ignore slope.
- Abundant scaling relations can be derived.
- Can take R_n , R_ℓ , and d as three independent parameters necessary to describe all 2-d branching networks.
- For scaling laws, only $h = \ln R_\ell / \ln R_n$ and d are needed.
- Laws can be extended nicely to laws of distributions.
- Numerous models of branching network evolution exist: nothing rock solid yet.
