## Law and Order, Special Science Edition: Truthicide Department

“In the scientific integrity system known as peer review, the people are represented by two highly overlapping yet equally important groups: the independent scientists who review papers and the scientists who punish those who publish garbage. This is one of their stories.”

$$P = c M^\alpha$$

Prefactor  $c$  depends on **body plan** and **body temperature**:

Birds	39–41 °C
Eutherian Mammals	36–38 °C
Marsupials	34–36 °C
Monotremes	30–31 °C

# The prevailing belief of the Church of Quarterology:

Most obvious concern:

$$3/4 - 2/3 = 1/12$$

- An exponent higher than  $2/3$  points suggests a fundamental inefficiency in biology.
- Organisms must somehow be running 'hotter' than they need to balance heat loss.

# What one might expect:

$\alpha = 2/3$  because ...

- Dimensional analysis suggests an energy balance surface law:

$$P \propto S \propto V^{2/3} \propto M^{2/3}$$

- Assumes isometric scaling (not quite the spherical cow).
- Lognormal fluctuations:** Gaussian fluctuations in  $\log_{10} P$  around  $\log_{10} cM^\alpha$ .
- Stefan-Boltzmann law** for radiated energy:

$$\frac{dE}{dt} = \sigma \epsilon S T^4 \propto S$$

# Related putative scalings:

Wait! There's more!:

- number of capillaries  $\propto M^{3/4}$
- time to reproductive maturity  $\propto M^{1/4}$
- heart rate  $\propto M^{-1/4}$
- cross-sectional area of aorta  $\propto M^{3/4}$
- population density  $\propto M^{-3/4}$

# The great 'law' of heartbeats:

Assuming:

- Average lifespan  $\propto M^\beta$
- Average heart rate  $\propto M^{-\beta}$
- Irrelevant but perhaps  $\beta = 1/4$ .

Then:

- Average number of heart beats in a lifespan  $\approx$  (Average lifespan)  $\times$  (Average heart rate)  $\propto M^{\beta-\beta} \propto M^0$
- Number of heartbeats per life time is independent of organism size!
- $\approx 1.5$  billion ....

"A general scaling law reveals why the largest animals are not the fastest"   
Hirt et al.,  
Nature Ecology & Evolution, 1, 1116, 2017. [23]

Figure 1 Concept of time-dependent and mass-dependent realized maximum speed of animals. a. Acceleration of animals follows a saturation curve (solid lines) approaching the theoretical maximum speed (dotted lines) depending on body mass (colour code). b. The time available for acceleration increases with body mass following a power law  $a \propto M^g$ . This critical time determines the realized maximum speed (c), yielding a hump-shaped increase of maximum speed with body mass (d).

# From PoCS, the Prequel to CocoNuTs:

"How fast do living organisms move: Maximum speeds from bacteria to elephants and whales"   
Meyer-Vernet and Rospars,  
American Journal of Physics, 83, 719-722,  
2015. [35]

Fig. 1. Maximum relative speed versus body mass for 202 running species (157 mammals plotted in magenta and 45 non-mammals plotted in green), 127 swimming species and 91 micro-organisms (plotted in blue). The sources of the data are given in Ref. 16. The solid line is the maximum relative speed (Eq. (13)) estimated in Sec. III. The human world records are plotted as asterisks (upper for running and lower for swimming). Some examples of organisms of various masses are sketched in black (drawings by François Meyer).

# Theoretical story:

Figure 4 Predicting the maximum speed of extant species with the time-dependent model. The model prediction (grey line) is fitted to data of extant species (grey circles) and extended to higher body masses. Speed data for dinosaurs (green triangles) come from detailed morphological model calculations (Tables 1) and were not used to obtain model parameters.

- Maximum speed increases with size:  $v_{max} = aM^b$
- Takes a while to get going:  $v(t) = v_{max}(1 - e^{-kt})$
- $k \sim F_{max}/M \sim cM^{d-1}$   
Literature:  $0.75 \lesssim d \lesssim 0.94$
- Acceleration time = depletion time for anaerobic energy:  $\tau \sim fM^g$  Literature:  $0.76 \lesssim g \lesssim 1.27$
- $v_{max} = aM^b (1 - e^{-hM^d})$
- $i = d - 1 + g$  and  $h = cf$

## An unsolved truthicide:

### So many questions ...

- Did the truth kill a theory? Or did a theory kill the truth?
- Or was the truth killed by just a lone, lowly hypothesis?
- Does this go all the way to the top?  
To the National Academies of Science?
- Is 2/3-scaling really dead?
- Could 2/3-scaling have faked its own death?
- What kind of people would vote on scientific facts?

## Linear regression

Important:

- Ordinary Least Squares (OLS) Linear regression is only appropriate for analyzing a dataset  $\{(x_i, y_i)\}$  when we know the  $x_i$  are measured without error.
- Here we assume that measurements of mass  $M$  have less error than measurements of metabolic rate  $B$ .
- Linear regression assumes Gaussian errors.

## Measuring exponents

More on regression:

- If (a) we don't know what the errors of either variable are,
- or (b) no variable can be considered independent,
- then we need to use Standardized Major Axis Linear Regression.<sup>[43, 41]</sup>
- (aka Reduced Major Axis = RMA.)

## Measuring exponents

For Standardized Major Axis Linear Regression:

$$\text{slope}_{\text{SMA}} = \frac{\text{standard deviation of } y \text{ data}}{\text{standard deviation of } x \text{ data}}$$

- Very simple!
- Minimization of sum of areas of triangles induced by vertical and horizontal residuals with best fit line.
- The only linear regression that is **Scale invariant**.
- Attributed to Nobel Laureate economist Paul Samuelson<sup>[43]</sup> but discovered independently by others.
- #somuchwin

# Measuring exponents

Relationship to ordinary least squares regression is simple:

$$\begin{aligned} \text{slope}_{\text{SMA}} &= r^{-1} \times \text{slope}_{\text{OLS } y \text{ on } x} \\ &= r \times \text{slope}_{\text{OLS } x \text{ on } y} \end{aligned}$$

where  $r$  = standard correlation coefficient:

$$r = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}}$$

🌀 Groovy upshot: If (1) a paper uses OLS regression when RMA would be appropriate, and (2)  $r$  is reported, we can figure out the RMA slope. [41, 29]

- 🌀 Disparity between slopes for  $y$  on  $x$  and  $x$  on  $y$  regressions is a factor of  $r^2$  ( $r^{-2}$ )
- 🌀 (Rayner uses  $\rho$  for  $r$ .)
- 🌀 Here:  $r^2 = .435^2 = 0.189$ , and  $r^{-2} = .435^{-2} = 2.29^2 = 5.285$ .
- 🌀 See also: LaBarbera [29] (who resigned ...)

# Fluctuations—Things look normal ...

- 🌀  $P(B|M) = 1/M^{2/3} f(B/M^{2/3})$
- 🌀 Use a Kolmogorov-Smirnov test.

# Hypothesis testing

Test to see if  $\alpha'$  is consistent with our data  $\{(M_i, B_i)\}$ :

$$H_0 : \alpha = \alpha' \text{ and } H_1 : \alpha \neq \alpha'$$

- 🌀 Assume each  $B_i$  (now a random variable) is normally distributed about  $\alpha' \log_{10} M_i + \log_{10} c$ .
- 🌀 Follows that the measured  $\alpha$  for one realization obeys a  $t$  distribution with  $N - 2$  degrees of freedom.
- 🌀 Calculate a  $p$ -value: probability that the measured  $\alpha$  is as least as different to our hypothesized  $\alpha'$  as we observe.
- 🌀 See, for example, DeGroot and Scherish, "Probability and Statistics." [11]

## Analysis of residuals

We use the spiffing Spearman Rank-Order Correlation Coefficient

Basic idea:

Given  $\{(x_i, y_i)\}$ , rank the  $\{x_i\}$  and  $\{y_i\}$  separately from smallest to largest. Call these ranks  $R_i$  and  $S_i$ .

Now calculate correlation coefficient for ranks,  $r_s$ :

$$r_s = \frac{\sum_{i=1}^n (R_i - \bar{R})(S_i - \bar{S})}{\sqrt{\sum_{i=1}^n (R_i - \bar{R})^2} \sqrt{\sum_{i=1}^n (S_i - \bar{S})^2}}$$

Perfect correlation:  $x_i$ 's and  $y_i$ 's both increase monotonically.

## Analysis of residuals

We assume all rank orderings are equally likely:

$r_s$  is distributed according to a Student's  $t$ -distribution with  $N - 2$  degrees of freedom.

Excellent feature: Non-parametric—real distribution of  $x$ 's and  $y$ 's doesn't matter.

Bonus: works for non-linear monotonic relationships as well.

See Numerical Recipes in C/Fortran which contains many good things.

## Analysis of residuals

- Presume an exponent of your choice:  $2/3$  or  $3/4$ .
- Fit the prefactor ( $\log_{10} c$ ) and then examine the residuals:

$$r_i = \log_{10} B_i - (\alpha' \log_{10} M_i - \log_{10} c).$$

- $H_0$ : residuals are uncorrelated  
 $H_1$ : residuals are correlated.
- Measure the correlations in the residuals and compute a  $p$ -value.

## Other approaches to measuring exponents:

- Clauset, Shalizi, Newman: "Power-law distributions in empirical data"<sup>[10]</sup> SIAM Review, 2009.
- See Clauset's page on [measuring power law exponents](#) (code, other goodies).
- See [this collection of tweets](#) for related amusement.

## Impure scaling?:

- So: The exponent  $\alpha = 2/3$  works for all birds and mammals up to 10–30 kg
- For mammals > 10–30 kg, maybe we have a new scaling regime
- Possible connection?: Economos (1983)—limb length break in scaling around 20 kg<sup>[15]</sup>
- But see later: non-isometric growth leads to lower metabolic scaling. Oops.

## Mysterious allometric scaling in river networks

- 1957: J. T. Hack<sup>[19]</sup> "Studies of Longitudinal Stream Profiles in Virginia and Maryland"

$$\ell \sim a^h$$

$$h \sim 0.6$$

- Anomalous scaling: we would expect  $h = 1/2$  ...
- Subsequent studies:  $0.5 \lesssim h \lesssim 0.6$
- Another quest to find [universality/god](#) ...
- A catch: studies done on small scales.

"Size and shape in biology"

T. McMahon,

Science, 179, 1201–1204, 1973. [32]

Fig. 3. (a) Chest circumference,  $d_c$ , plotted against body weight,  $W$ , for five species of primates. The broken lines represent the standard error in this least-squares fit (adapted from [27]). The model proposed here, whereby each length,  $L$ , increases as the  $3/4$  power of diameter,  $d$ , is illustrated for two weights differing by a factor of 16. (b) Body surface area plotted against weight for vertebrates. The animal data are reasonably well fitted by the stretched cylinder model (adapted from [6]).

## Earlier theories (1973–):

### Building on the surface area idea:

McMahon (70's, 80's): Elastic Similarity [32, 34]

Idea is that organismal shapes scale allometrically with  $1/4$  powers (like trees ...)

Disastrously, cites Hemmingsen [21] for surface area data.

Appears to be true for ungulate legs ... [33]

Metabolism and shape never properly connected.

## Earlier theories (1977):

### Building on the surface area idea ...

Blum (1977) [5] speculates on four-dimensional biology:

$$P \propto M^{(d-1)/d}$$

$d = 3$  gives  $\alpha = 2/3$

$d = 4$  gives  $\alpha = 3/4$

So we need another dimension ...

Obviously, a bit silly... [46]

## Not so fast ...

Actually, model shows:

- $P \propto M^{3/4}$  does not follow for pulsatile flow
- networks are not necessarily fractal.

Do find:

- Murray's cube law (1927) for outer branches: [37]

$$r_0^3 = r_1^3 + r_2^3$$

- Impedance is distributed evenly.
- Can still assume networks are fractal.

## Connecting network structure to $\alpha$

- Ratios of network parameters:

$$R_n = \frac{n_{k+1}}{n_k}, R_\ell = \frac{\ell_{k+1}}{\ell_k}, R_r = \frac{r_{k+1}}{r_k}$$

- Number of capillaries  $\propto P \propto M^\alpha$ .

$$\Rightarrow \alpha = -\frac{\ln R_n}{\ln R_r^2 R_\ell}$$

(also problematic due to prefactor issues)

Obliviously soldiering on, we could assert:

- area-preservingness:  $R_r = R_n^{-1/2} \Rightarrow \alpha = 3/4$
- space-fillingness:  $R_\ell = R_n^{-1/3}$

## Impedance measures:

- Poiseuille flow (outer branches):

$$Z = \frac{8\mu}{\pi} \sum_{k=0}^N \frac{\ell_k}{r_k^4 N_k}$$

- Pulsatile flow (main branches):

$$Z \propto \sum_{k=0}^N \frac{h_k^{1/2}}{r_k^{5/2} N_k}$$

- Wheel out Lagrange multipliers ...
- Poiseuille gives  $P \propto M^1$  with a logarithmic correction.
- Pulsatile calculation explodes into flames.

Let's never talk about this again:

“The fourth dimension of life: Fractal geometry and allometric scaling of organisms”

West, Brown, and Enquist, Science Magazine, **284**, 1677–1679, 1999. [54]

- No networks: Scaling argument for energy exchange area  $a$ .
- Distinguish between biological and physical length scales (distance between mitochondria versus cell radius).
- Buckingham  $\pi$  action. [9]
- Arrive at  $a \propto M^{D/D+1}$  and  $\ell \propto M^{1/D}$ .
- New disaster: after going on about fractality of  $a$ , then state  $v \propto a\ell$  in general.

Yah:

**Figure 1 | Curvature in metabolic scaling.** a. Linear (red) and quadratic (blue) fits (not including temperature) of  $\log_{10}B/W$  versus  $\log_{10}M$ . The orca (green square) and Asian elephant (red & turquoise square at larger mass) are not included in the fit, but are predicted well. Differences in the quality of fit are best seen in terms of the conditional mean of the error, estimated by the loess (locally-weighted scatterplot smoothing) fit of the residuals (Supplementary Information). See Table 1 for the values of the coefficients obtained from the fit. b. Slope of the quadratic fit (including temperature) with pointwise 95% confidence intervals (black). The slope of the power law fit (red) and models with fixed 2/3 and 3/4 exponents (black) are included for comparison. This panel suggests that exponents estimated by assuming a power law will be highly sensitive to the mass range of the data set used, as shown in Fig. 2.

## Geometric argument

- Allometrically growing regions:

- Have  $d$  length scales which scale as

$$L_i \propto V^{\gamma_i} \text{ where } \gamma_1 + \gamma_2 + \dots + \gamma_d = 1.$$

- For **isometric** growth,  $\gamma_i = 1/d$ .
- For **allometric** growth, we must have at least two of the  $\{\gamma_i\}$  being different

# Minimal network volume:

We add one more element:

- Vessel cross-sectional area may vary with distance from the source.
- Flow rate increases as cross-sectional area decreases.
- e.g., a collection network may have vessels tapering as they approach the central sink.
- Find that vessel volume  $v$  must scale with vessel length  $l$  to affect overall system scalings.

# Minimal network volume:

Effecting scaling:

- Consider vessel radius  $r \propto (l + 1)^{-\epsilon}$ , tapering from  $r = r_{\text{max}}$  where  $\epsilon \geq 0$ .
- Gives  $v \propto l^{1-2\epsilon}$  if  $\epsilon < 1/2$
- Gives  $v \propto 1 - l^{-(2\epsilon-1)} \rightarrow 1$  for large  $l$  if  $\epsilon > 1/2$
- Previously, we looked at  $\epsilon = 0$  only.

# Minimal network volume:

For  $0 \leq \epsilon < 1/2$ , approximate network volume by integral over region:

$$\min V_{\text{net}} \propto \int_{\Omega_{d,D}(V)} \rho \|\vec{x}\|^{1-2\epsilon} d\vec{x}$$

Insert question from assignment 4

$$\propto \rho V^{1+\gamma_{\text{max}}(1-2\epsilon)} \text{ where } \gamma_{\text{max}} = \max_i \gamma_i.$$

For  $\epsilon > 1/2$ , find simply that

$$\min V_{\text{net}} \propto \rho V$$

- So if supply lines can taper fast enough and without limit, minimum network volume can be made negligible.

For  $0 \leq \epsilon < 1/2$ :

$$\min V_{\text{net}} \propto \rho V^{1+\gamma_{\text{max}}(1-2\epsilon)}$$

If scaling is **isometric**, we have  $\gamma_{\text{max}} = 1/d$ :

$$\min V_{\text{net/iso}} \propto \rho V^{1+(1-2\epsilon)/d}$$

If scaling is **allometric**, we have  $\gamma_{\text{max}} = \gamma_{\text{allo}} > 1/d$ :  
and

$$\min V_{\text{net/allo}} \propto \rho V^{1+(1-2\epsilon)\gamma_{\text{allo}}}$$

Isometrically growing volumes **require less network volume** than allometrically growing volumes:

$$\frac{\min V_{\text{net/iso}}}{\min V_{\text{net/allo}}} \rightarrow 0 \text{ as } V \rightarrow \infty$$

## Blood networks

Velocity at capillaries and aorta approximately constant across body size [51]:  $\epsilon = 0$ .

**Material costly**  $\Rightarrow$  expect lower optimal bound of  $V_{\text{net}} \propto \rho V^{(d+1)/d}$  to be followed closely.

For cardiovascular networks,  $d = D = 3$ .

Blood volume scales linearly with body volume [47],  $V_{\text{net}} \propto V$ .

Sink density must  $\therefore$  decrease as volume increases:

$$\rho \propto V^{-1/d}.$$

Density of suppliable sinks **decreases** with organism size.

For  $\epsilon > 1/2$ :

$$\min V_{\text{net}} \propto \rho V$$

Network volume scaling is now independent of overall shape scaling.

## Limits to scaling

Can argue that  $\epsilon$  must effectively be 0 for real networks over large enough scales.

Limit to how fast material can move, and how small material packages can be.

e.g., blood velocity and blood cell size.

## Blood networks

Then  $P$ , the rate of overall energy use in  $\Omega$ , can at most scale with volume as

$$P \propto \rho V \propto \rho M \propto M^{(d-1)/d}$$

For  $d = 3$  dimensional organisms, we have

$$P \propto M^{2/3}$$

Including other constraints may raise scaling exponent to a higher, less efficient value.

This is a really clean slide

**Exciting bonus:** Scaling obtained by the supply network story and the surface-area law **only match** for isometrically growing shapes.  
Insert question from assignment 4 [↗](#)

## Recall:

- The exponent  $\alpha = 2/3$  works for all birds and mammals up to 10–30 kg
- For mammals > 10–30 kg, maybe we have a new scaling regime
- Economos: limb length break in scaling around 20 kg
- White and Seymour, 2005: unhappy with large herbivore measurements. Find  $\alpha \approx 0.686 \pm 0.014$

## Hack's law

- Volume of water in river network can be calculated by adding up basin areas
- Flows sum in such a way that

$$V_{\text{net}} = \sum_{\text{all pixels}} a_{\text{pixel } i}$$

- Hack's law again:

$$\ell \sim a^h$$

- Can argue

$$V_{\text{net}} \propto V_{\text{basin}}^{1+h} = a_{\text{basin}}^{1+h}$$

where  $h$  is Hack's exponent.

- $\therefore$  minimal volume calculations gives

$$h = 1/2$$

## Prefactor:

Stefan-Boltzmann law:

$$\frac{dE}{dt} = \sigma S T^4$$

where  $S$  is surface and  $T$  is temperature.

- Very rough estimate of prefactor based on scaling of normal mammalian body temperature and surface area  $S$ :

$$B \approx 10^5 M^{2/3} \text{ erg/sec.}$$

- Measured for  $M \leq 10$  kg:

$$B = 2.57 \times 10^5 M^{2/3} \text{ erg/sec.}$$

## River networks

- View river networks as collection networks.
- Many sources and one sink.
- $\epsilon$ ?
- Assume  $\rho$  is constant over time and  $\epsilon = 0$ :

$$V_{\text{net}} \propto \rho V^{(d+1)/d} = \text{constant} \times V^{3/2}$$

- Network volume grows faster than basin 'volume' (really area).
- It's all okay: Landscapes are  $d=2$  surfaces living in  $D=3$  dimensions.
- Streams can grow not just in width but in depth ...
- If  $\epsilon > 0$ ,  $V_{\text{net}}$  will grow more slowly but  $3/2$  appears to be confirmed from real data.

## Some people understand it's truly a disaster: ↗

### Peter Sheridan Dodds, Theoretical Biology's Buzzkill

By Mark Changizi | February 9th 2010 03:24 PM | 1 comment | [Print](#) | [E-mail](#) | [Track Comments](#)

[Share](#) / [Save](#) / [Facebook](#) / [Twitter](#) / [Like](#)

There is an apocryphal story about a graduate mathematics student at the University of Virginia studying the properties of certain mathematical objects. In his fifth year some killjoy bastard elsewhere published a paper proving that there are no such mathematical objects. He dropped out of the program, and I never did hear where he is today. He's probably making my cappuccino right now.

This week, a professor named Peter Sheridan Dodds published a new paper in *Physical Review Letters* further fleshing out a theory concerning why a  $2/3$  power law may apply for metabolic rate. The  $2/3$  law says that metabolic rate in animals rises as the  $2/3$  power of body mass. It was in a 2001 *Journal of Theoretical Biology* paper that he first argued that perhaps a  $2/3$  law applies, and that paper—along with others such as the one that just appeared—is what has put him in the Killjoy Hall of Fame. The University of Virginia's killjoy was a mere amateur.

## Conclusion

- 🔗 Supply network story consistent with dimensional analysis.
- 🔗 Isometrically growing regions can be more efficiently supplied than allometrically growing ones.
- 🔗 Ambient and region dimensions matter ( $D = d$  versus  $D > d$ ).
- 🔗 Deviations from optimal scaling suggest inefficiency (e.g., gravity for organisms, geological boundaries).
- 🔗 Actual details of branching networks not that important.
- 🔗 Exact nature of self-similarity varies.
- 🔗  $2/3$ -scaling lives on, largely in hiding.
- 🔗  $3/4$ -scaling? Jury ruled a mistrial.
- 🔗 The truth will out. Maybe.
