Robustness

- Many complex systems are prone to cascading catastrophic failure: exciting!!!
 - Blackouts
 - Disease outbreaks
 - Wildfires
 - Earthquakes
 - Organisms, individuals and societies

 - Cities
 - Myths: Achilles.
- But complex systems also show persistent robustness (not as exciting but important...)
- Robustness and Failure may be a power-law story...

System robustness may result from

Robustness

- 1. Evolutionary processes
- 2. Engineering/Design
- Idea: Explore systems optimized to perform under uncertain conditions.
- A The handle: 'Highly Optimized Tolerance' (HOT) [4, 5, 6, 10]
- The catchphrase: Robust yet Fragile
- 🚵 The people: Jean Carlson and John Doyle 🗹
- Great abstracts of the world #73: "There aren't any." [7]

Robustness

Features of HOT systems: [5, 6]

- High performance and robustness
- Designed/evolved to handle known stochastic environmental variability
- Fragile in the face of unpredicted environmental
- Highly specialized, low entropy configurations
- Power-law distributions appear (of course...)

@pocsvox

System

Robustness

HOT combines things we've seen:

- Variable transformation
- Constrained optimization
- Need power law transformation between variables: $(Y = X^{-\alpha})$
- Recall PLIPLO is bad...
- MIWO is good: Mild In, Wild Out

Robustness HOT theory

Self-Organized Criti-

References

Robustness

Forest fire example: [5]

- \$ Square $N \times N$ grid
- Sites contain a tree with probability ρ = density
- Sites are empty with probability 1ρ
- \clubsuit Fires start at location (i, j) according to some distribution $P_{i,i}$
- Fires spread from tree to tree (nearest neighbor
- Connected clusters of trees burn completely
- Empty sites block fire
- Best case scenario: Build firebreaks to maximize average # trees left intact given one spark

Robustness

Forest fire example: [5]

- Build a forest by adding one tree at a time
- A Test D ways of adding one tree
- \clubsuit Average over P_{ij} = spark probability
- A D=1: random addition
- $A = N^2$: test all possibilities

Measure average area of forest left untouched

- $\Re f(c)$ = distribution of fire sizes c (= cost)
- \Re Yield = $Y = \rho \langle c \rangle$

Robustness

Specifics:

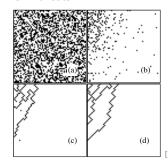

$$P_{ij} = P_{i;a_x,b_x} P_{j;a_y,b_y}$$

where

$$P_{i;a,b} \propto e^{-[(i+a)/b]^2}$$

- A In the original work, $b_u > b_x$
- Distribution has more width in y direction.

HOT Forests

N = 64

- (a) D = 1
- (b) D = 2
- (c) D=N(d) $D = N^2$

 P_{ij} has a Gaussian decay

- Optimized forests do well on average (robustness)
- But rare extreme events occur (fragility)

HOT Forests

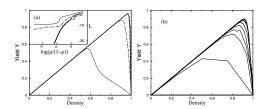

FIG. 2. Yield vs density $Y(\rho)$: (a) for design parameters D =1 (dotted curve), 2 (dot-dashed), N (long dashed), and N^2 (solid) with N = 64, and (b) for D = 2 and $N = 2, 2^2, ..., 2^7$ running from the bottom to top curve. The results have been averaged over 100 runs. The inset to (a) illustrates corresponding loss functions $L = \log[\langle f \rangle/(1 - \langle f \rangle)]$, on a scale which more clearly differentiates between the curves.

PoCS @pocsvox System Robustness

HOT theory

HOT Forests:

A = 'the average density of trees left unburned in a configuration after a single spark hits.' [5]

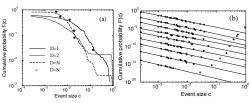

FIG. 3. Cumulative distributions of events F(c): (a) at peak yield for D = 1, 2, N, and N^2 with N = 64, and (b) for D = 1 N^2 , and N = 64 at equal density increments of 0.1, ranging at $\rho = 0.1$ (bottom curve) to $\rho = 0.9$ (top curve).

HOT theory Narrative cau

HOT forests nutshell:

- Highly structured
- Power law distribution of tree cluster sizes for a broad range of ρ_r including below ρ_c .
- & No specialness of ρ_c
- Forest states are tolerant
- Uncertainty is okay if well characterized
- \Re If $P_{i,i}$ is characterized poorly or changes too fast, failure becomes highly likely
- Growth is key to toy model which is both algorithmic and physical.
- A HOT theory is more general than just this toy model.

HOT forests—Real data:

"Complexity and Robustness," Carlson & Dolye [6]

These are CCDFs (Eek: $P, \mathcal{P}(l \geq l_i)$)

- PLR = probability-lossresource.
- Minimize cost subject to resource (barrier) constraints: $C = \sum_{i} p_{i} l_{i}$ given $l_i = f(r_i)$ and $\sum r_i \leq R$.

DC = Data Compression.

& Horror: log. Screaming: "The base! What is the base!? You monsters!"

HOT theory:

The abstract story, using figurative forest fires: Robustness HOT theory

- \mathcal{L} Given some measure of failure size y_i and correlated resource size x_i with relationship $y_i = x_i^{-\alpha}$, $i = 1, \dots, N_{\mathsf{sites}}$.
- Design system to minimize $\langle y \rangle$ subject to a constraint on the x_i .
- Minimize cost:

$$C = \sum_{i=1}^{N_{\mathrm{Sites}}} \mathbf{Pr}(y_i) y_i$$

Subject to $\sum_{i=1}^{N_{\text{sites}}} x_i = \text{constant.}$

1. Cost: Expected size of fire:

WW |8 夕 Q № 21 of 38

PoCS @pocsvox System

Robustness

References

 $C_{ ext{firewalls}} \propto \sum_{i=1}^{N_{ ext{sites}}} a_i^{1/2} a_i^{-1}.$

 $C_{\mathsf{fire}} \propto \sum_{i=1}^{N_{\mathsf{sites}}} p_i a_i.$

 a_i = area of *i*th site's region, and p_i = avg. prob. of fire

We are assuming isometry.

at *i*th site over some time frame.

- ightharpoonup In d dimensions, 1/2 is replaced by (d-1)/d
- 3. Insert question from assignment 7 d to find:

2. Constraint: building and maintaining firewalls.

Per unit area, and over same time frame:

 $\Pr(a_i) \propto a_i^{-\gamma}$

UNN O

•9 q (~ 14 of 38

Continuum version:

Cost function:

$$\langle C \rangle = \int C(\vec{x}) p(\vec{x}) \mathrm{d}\vec{x}$$

where C is some cost to be evaluated at each point in space \vec{x} (e.g., $V(\vec{x})^{\alpha}$), and $p(\vec{x})$ is the probability an Ewok jabs position \vec{x} with a sharpened stick (or equivalent).

2. Constraint:

$$\int R(\vec{x}) d\vec{x} = c$$

where c is a constant.

Claim/observation is that typically [4]

$$V(\vec{x}) \sim R^{-\beta}(\vec{x})$$

 $\ensuremath{\mathfrak{S}}$ For spatial systems with barriers: $\beta = d$.

SOC theory

SOC = Self-Organized Criticality

- & Idea: natural dissipative systems exist at 'critical states';
- Analogy: Ising model with temperature somehow self-tuning;
- Power-law distributions of sizes and frequencies arise 'for free';
- Introduced in 1987 by Bak, Tang, and Weisenfeld [3, 2, 8]: "Self-organized criticality - an explanation of 1/f noise" (PRL, 1987);
- Problem: Critical state is a very specific point;
- Self-tuning not always possible;
- Much criticism and arguing...

'How Nature Works: the Science of Self-Organized Criticality" 3, 🗹 by Per Bak (1997). [2]

COLD forests

Avoidance of large-scale failures

- Constrained Optimization with Limited Deviations [9]
- Weight cost of larges losses more strongly
- Increases average cluster size of burned trees...
- & ... but reduces chances of catastrophe
- Power law distribution of fire sizes is truncated

Cutoffs

Robustness Narrative causalit Self-Organized Criticali

References

Observed:

Robustness

Power law distributions often have an exponential

 $P(x) \sim x^{-\gamma} e^{-x/x_c}$

where x_c is the approximate cutoff scale.

May be Weibull distributions:

 $P(x) \sim x^{-\gamma} e^{-a\, x^{-\gamma+1}}$
