## Scale-free networks

- Scale-free networks are **not fractal** in any sense.
- Usually talking about networks whose links are **abstract, relational, informational, ... (non-physical)**
- Primary example: hyperlink network of the Web
- Much arguing about whether or networks are 'scale-free' or not...

## Some real data (we are feeling brave):

### From Barabási and Albert's original paper [2]:

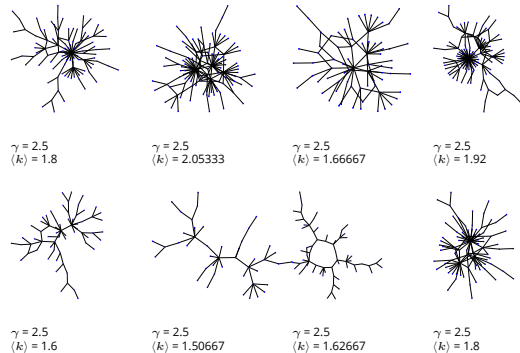

Fig. 1. The distribution function of connectivities for various large networks. (A) Actor collaboration graph with  $N = 212,250$  vertices and average connectivity  $\langle k \rangle = 28.78$ . (B) WWW,  $N = 325,729$ ,  $\langle k \rangle = 5.46$  (6). (C) Power grid data,  $N = 4941$ ,  $\langle k \rangle = 2.67$ . The dashed lines have slopes (A)  $\gamma_{\text{actor}} = 2.3$ , (B)  $\gamma_{\text{www}} = 2.1$  and (C)  $\gamma_{\text{power}} = 4$ .

## Scale-free networks

### The big deal:

- We move beyond describing networks to finding **mechanisms** for why certain networks are the way they are.

### A big deal for scale-free networks:

- How does the exponent  $\gamma$  depend on the mechanism?
- Do the mechanism details matter?

## BA model

- Barabási-Albert model = BA model.
- Key ingredients:  
**Growth and Preferential Attachment (PA).**
- Step 1: start with  $m_0$  disconnected nodes.
- Step 2:

- Growth—a new node appears at each time step  $t = 0, 1, 2, \dots$
- Each new node makes  $m$  links to nodes already present.
- Preferential attachment—Probability of connecting to  $i$ th node is  $\propto k_i$ .

- In essence, we have a **rich-gets-richer** scheme.
- Yes, we've seen this all before in Simon's model.

## BA model

- Definition:**  $A_k$  is the attachment kernel for a node with degree  $k$ .
- For the original model:

$$A_k = k$$

- Definition:**  $P_{\text{attach}}(k, t)$  is the attachment probability.
- For the original model:

$$P_{\text{attach}}(\text{node } i, t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{\text{max}}(t)} k N_k(t)}$$

where  $N(t) = m_0 + t$  is # nodes at time  $t$  and  $N_k(t)$  is # degree  $k$  nodes at time  $t$ .

## Scale-free networks

- Networks with power-law degree distributions have become known as **scale-free** networks.
- Scale-free refers specifically to the **degree distribution** having a **power-law decay** in its tail:

$$P_k \sim k^{-\gamma} \text{ for 'large' } k$$

- One of the seminal works in complex networks:

"Emergence of scaling in random networks"  
Barabási and Albert,  
Science, **286**, 509–511, 1999. [2]

Times cited: [~ 23,532](#) (as of October 8, 2015)

- Somewhat misleading nomenclature...

## Approximate analysis

- When  $(N + 1)$ th node is added, the expected increase in the degree of node  $i$  is

$$E(k_{i,N+1} - k_{i,N}) \simeq m \frac{k_{i,N}}{\sum_{j=1}^{N(t)} k_j(t)}$$

- Assumes probability of being connected to is **small**.
- Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.
- Approximate  $k_{i,N+1} - k_{i,N}$  with  $\frac{d}{dt}k_{i,t}$ :

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where  $t = N(t) - m_0$ .

- Deal with denominator: each added node brings  $m$  new edges.

$$\therefore \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

- The node degree equation now simplifies:

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = m \frac{k_i(t)}{2mt} = \frac{1}{2t}k_i(t)$$

- Rearrange and solve:

$$\frac{dk_i(t)}{k_i(t)} = \frac{dt}{2t} \Rightarrow \boxed{k_i(t) = c_i t^{1/2}}$$

- Next find  $c_i$  ...

- Know  $i$ th node appears at time

$$t_{i,start} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

- So for  $i > m_0$  (exclude initial nodes), we must have

$$k_i(t) = m \left( \frac{t}{t_{i,start}} \right)^{1/2} \text{ for } t \geq t_{i,start}$$

- All node degrees grow as  $t^{1/2}$  but later nodes have larger  $t_{i,start}$  which flattens out growth curve.
- First-mover advantage: Early nodes do **best**.
- Clearly, a Ponzi scheme.

## We are already at the Zipf distribution:

- Degree of node  $i$  is the size of the  $i$ th ranked node:

$$k_i(t) = m \left( \frac{t}{t_{i,start}} \right)^{1/2} \text{ for } t \geq t_{i,start}$$

- From before:

$$t_{i,start} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

so  $t_{i,start} \sim i$  which is the rank.

- We then have:

$$k_i \propto i^{-1/2} = i^{-\alpha}$$

- Our connection  $\alpha = 1/(\gamma - 1)$  or  $\gamma = 1 + 1/\alpha$  then gives

$$\gamma = 1 + 1/(1/2) = 3.$$

- $m = 3$
- $t_{i,start} = 1, 2, 5, \text{ and } 10.$

## Degree distribution

- So what's the degree distribution at time  $t$ ?
- Use fact that birth time for added nodes is distributed uniformly between time 0 and  $t$ :

$$\Pr(t_{i,start})dt_{i,start} \simeq \frac{dt_{i,start}}{t}$$

- Also use

$$k_i(t) = m \left( \frac{t}{t_{i,start}} \right)^{1/2} \Rightarrow t_{i,start} = \frac{m^2 t}{k_i(t)^2}$$

Transform variables—Jacobian:

$$\frac{dt_{i,start}}{dk_i} = -2 \frac{m^2 t}{k_i(t)^3}$$

## Degree distribution

$$\begin{aligned} \Pr(k_i)dk_i &= \Pr(t_{i,start})dt_{i,start} \\ &= \Pr(t_{i,start})dk_i \left| \frac{dt_{i,start}}{dk_i} \right| \\ &= \frac{1}{t} dk_i 2 \frac{m^2 t}{k_i(t)^3} \\ &= 2 \frac{m^2}{k_i(t)^3} dk_i \\ &\propto k_i^{-3} dk_i. \end{aligned}$$

## Degree distribution

- We thus have a very specific prediction of  $\Pr(k) \sim k^{-\gamma}$  with  $\gamma = 3$ .
- Typical for real networks:  $2 < \gamma < 3$ .
- Range true more generally for events with size distributions that have power-law tails.
- $2 < \gamma < 3$ : finite mean and 'infinite' variance (**wild**)
- In practice,  $\gamma < 3$  means variance is governed by upper cutoff.
- $\gamma > 3$ : finite mean and variance (**mild**)

## Back to that real data:

From Barabási and Albert's original paper [2]:

Fig. 1. The distribution function of connectivities for various large networks. (A) Actor collaboration graph with  $N = 212,250$  vertices and average connectivity  $\langle k \rangle = 28.78$ . (B) WWW,  $N = 325,729$ ,  $\langle k \rangle = 5.46$  (6). (C) Power grid data,  $N = 4941$ ,  $\langle k \rangle = 2.67$ . The dashed lines have slopes (A)  $\gamma_{\text{actor}} = 2.3$ , (B)  $\gamma_{\text{www}} = 2.1$  and (C)  $\gamma_{\text{power}} = 4$ .

## Preferential attachment through randomness

- Instead of attaching preferentially, allow new nodes to attach randomly.
- Now add an **extra step**: new nodes then connect to some of their friends' friends.
- Can also do this **at random**.
- Assuming the existing network is random, we know probability of a **random friend** having degree  $k$  is

$$Q_k \propto kP_k$$

- So **rich-gets-richer** scheme can now be seen to work in a natural way.

## Robustness

from Albert et al., 2000

26 of 55

## Things to do and questions

- Vary attachment kernel.
- Vary mechanisms:
  - Add edge deletion
  - Add node deletion
  - Add edge rewiring
- Deal with directed versus undirected networks.
- Important Q.:** Are there distinct universality classes for these networks?
- Q.:** How does changing the model affect  $\gamma$ ?
- Q.:** Do we need preferential attachment and growth?
- Q.:** Do model details matter? Maybe ...

## Preferential attachment

- Let's look at preferential attachment (PA) a little more closely.
- PA implies arriving nodes have **complete knowledge** of the existing network's degree distribution.
- For example: If  $P_{\text{attach}}(k) \propto k$ , we need to determine the constant of proportionality.
- We need to know what everyone's degree is...
- PA is an **outrageous** assumption of node capability.
- But a **very simple mechanism** saves the day...

26 of 55

## Robustness

- Scale-free networks are thus **robust to random failures yet fragile to targeted ones**.
- All very reasonable: **Hubs** are a big deal.
- But:** next issue is whether hubs are vulnerable or not.
- Representing all webpages as the same size node is obviously a stretch (e.g., google vs. a random person's webpage)
- Most connected nodes are either:
  - Physically larger nodes that may be harder to 'target'
  - or subnetworks of smaller, normal-sized nodes.
- Need to explore cost of various targeting schemes.

## Robustness

### Not a robust paper:

"The 'Robust yet Fragile' nature of the Internet" [2]  
Doyle et al.,  
Proc. Natl. Acad. Sci., **2005**, 14497-14502, 2005. [3]

- HOT networks versus scale-free networks
- Same degree distributions, different arrangements.
- Doyle *et al.* take a look at the actual Internet.

29 of 55

## Generalized model

### Fooling with the mechanism:

- 2001: Krapivsky & Redner (KR) [4] explored the **general attachment kernel**:

$$Pr(\text{attach to node } i) \propto A_k = k_i^\nu$$

- where  $A_k$  is the attachment kernel and  $\nu > 0$ .
- KR also looked at changing the details of the attachment kernel.
- KR model will be fully studied in CoNKS.

## Generalized model

- We'll follow KR's approach using rate equations.
- Here's the set up:

$$\frac{dN_k}{dt} = \frac{1}{A} [A_{k-1}N_{k-1} - A_k N_k] + \delta_{k1}$$

where  $N_k$  is the number of nodes of degree  $k$ .

- One node with one link is added per unit time.
- The **first term** corresponds to degree  $k - 1$  nodes becoming degree  $k$  nodes.
- The **second term** corresponds to degree  $k$  nodes becoming degree  $k - 1$  nodes.
- $A$  is the correct normalization (coming up).
- Seed with some initial network (e.g., a connected pair)
- Detail:  $A_0 = 0$

## Generalized model

- In general, probability of attaching to a **specific node** of degree  $k$  at time  $t$  is

$$\Pr(\text{attach to node } i) = \frac{A_k}{A(t)}$$

where  $A(t) = \sum_{k=1}^{\infty} A_k N_k(t)$ .

- E.g., for BA model,  $A_k = k$  and  $A = \sum_{k=1}^{\infty} k N_k(t)$ .
- For  $A_k = k$ , we have

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) = 2t$$

since one edge is being added per unit time.

- Detail: we are ignoring initial seed network's edges.

## Generalized model

- So now

$$\frac{dN_k}{dt} = \frac{1}{A} [A_{k-1}N_{k-1} - A_k N_k] + \delta_{k1}$$

becomes

$$\frac{dN_k}{dt} = \frac{1}{2t} [(k-1)N_{k-1} - kN_k] + \delta_{k1}$$

- As for BA method, look for steady-state growing solution:  $N_k = n_k t$ .
- We replace  $dN_k/dt$  with  $dn_k t/dt = n_k$ .
- We arrive at a difference equation:

$$n_k = \frac{1}{2t} [(k-1)n_{k-1}t - kn_k t] + \delta_{k1}$$

## Universality?

- As expected, we have the same result as for the BA model:

$$N_k(t) = n_k(t)t \propto k^{-3}t \text{ for large } k.$$

- Now: what happens if we start playing around with the attachment kernel  $A_k$ ?
- Again, we're asking if the result  $\gamma = 3$  **universal**?
- KR's natural modification:  $A_k = k^\nu$  with  $\nu \neq 1$ .
- But we'll first explore a more subtle modification of  $A_k$  made by Krapivsky/Redner<sup>[4]</sup>
- Keep  $A_k$  **linear in  $k$**  but tweak details.
- Idea:** Relax from  $A_k = k$  to  $A_k \sim k$  as  $k \rightarrow \infty$ .

## Universality?

- Recall we used the normalization:

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) \simeq 2t \text{ for large } t.$$

- We now have

$$A(t) = \sum_{k'=1}^{\infty} A_{k'} N_{k'}(t)$$

where we only know the asymptotic behavior of  $A_k$ .

- We assume that  $A = \mu t$
- We'll find  $\mu$  later and make sure that our assumption is consistent.
- As before, also assume  $N_k(t) = n_k t$ .

## Universality?

- For  $A_k = k$  we had

$$n_k = \frac{1}{2} [(k-1)n_{k-1} - kn_k] + \delta_{k1}$$

- This now becomes

$$n_k = \frac{1}{\mu} [A_{k-1}n_{k-1} - A_k n_k] + \delta_{k1}$$

$$\Rightarrow (A_k + \mu)n_k = A_{k-1}n_{k-1} + \mu\delta_{k1}$$

- Again two cases:

$$k = 1 : n_1 = \frac{\mu}{\mu + A_1}; \quad k > 1 : n_k = n_{k-1} \frac{A_{k-1}}{\mu + A_k}.$$

## Universality?

- Time for pure excitement: Find **asymptotic behavior** of  $n_k$  given  $A_k \rightarrow k$  as  $k \rightarrow \infty$ .
- For large  $k$ , we find:

$$n_k = \frac{\mu}{A_k} \prod_{j=1}^k \frac{1}{1 + \frac{\mu}{A_j}} \propto k^{-\mu-1}$$

- Since  $\mu$  depends on  $A_k$ , **details matter...**

## Universality?

- Now we need to find  $\mu$ .
- Our assumption again:  $A = \mu t = \sum_{k=1}^{\infty} N_k(t) A_k$
- Since  $N_k = n_k t$ , we have the simplification  $\mu = \sum_{k=1}^{\infty} n_k A_k$
- Now substitute in our expression for  $n_k$ :

$$1\mu = \sum_{k=1}^{\infty} \frac{\mu}{A_k} \prod_{j=1}^k \frac{1}{1 + \frac{\mu}{A_j}} A_k$$

- Closed form expression for  $\mu$ .
- We can solve for  $\mu$  in some cases.
- Our assumption that  $A = \mu t$  looks to be not too horrible.

## Universality?

- Consider tunable  $A_1 = \alpha$  and  $A_k = k$  for  $k \geq 2$ .
- Again, we can find  $\gamma = \mu + 1$  by finding  $\mu$ .
- Closed form expression for  $\mu$ :

$$\frac{\mu}{\alpha} = \sum_{k=2}^{\infty} \frac{\Gamma(k+1)\Gamma(2+\mu)}{\Gamma(k+\mu+1)}$$

#mathisfun

$$\mu(\mu-1) = 2\alpha \Rightarrow \mu = \frac{1 + \sqrt{1+8\alpha}}{2}.$$

- Since  $\gamma = \mu + 1$ , we have

$$0 \leq \alpha < \infty \Rightarrow 2 \leq \gamma < \infty$$

- Craziness...

## Sublinear attachment kernels

Rich-get-somewhat-richer:

$$A_k \sim k^\nu \text{ with } 0 < \nu < 1.$$

General finding by Krapivsky and Redner: [4]

$$n_k \sim k^{-\nu} e^{-c_1 k^{1-\nu}} + \text{correction terms}.$$

Stretched exponentials (truncated power laws).

aka Weibull distributions.

**Universality:** now details of kernel **do not matter**.

Distribution of degree is universal providing  $\nu < 1$ .

## Sublinear attachment kernels

Details:

For  $1/2 < \nu < 1$ :

$$n_k \sim k^{-\nu} e^{-\mu \left( \frac{k^{1-\nu} - 2^{1-\nu}}{1-\nu} \right)}$$

For  $1/3 < \nu < 1/2$ :

$$n_k \sim k^{-\nu} e^{-\mu \left( \frac{k^{1-\nu}}{1-\nu} + \frac{\mu^2}{2} \frac{k^{1-2\nu}}{1-2\nu} \right)}$$

And for  $1/(r+1) < \nu < 1/r$ , we have  $r$  pieces in exponential.

## Superlinear attachment kernels

Rich-get-much-richer:

$$A_k \sim k^\nu \text{ with } \nu > 1.$$

Now a **winner-take-all** mechanism.

One single node ends up being connected to almost all other nodes.

For  $\nu > 2$ , all but a finite # of nodes connect to one node.

## Nutshell:

Overview Key Points for Models of Networks:

Obvious connections with the vast extant field of graph theory.

But focus on dynamics is more of a physics/stat-mech/comp-sci flavor.

Two main areas of focus:

1. **Description:** Characterizing very large networks
2. **Explanation:** Micro story  $\Rightarrow$  Macro features

Some essential structural aspects are understood: degree distribution, clustering, assortativity, group structure, overall structure,...

Still much work to be done, especially with respect to dynamics... **#excitement**
