# Universality

- Sometimes **details don't matter too much.**
- Many-to-one mapping from micro to macro
- Suggests not all possible behaviors are available at higher levels of complexity.
- Universality means some things are fated.

## Large questions:

- How universal is universality?
- What are the possible long-time states (attractors) for a universe?

For your consideration  
References

# Fluid mechanics

- Fluid mechanics = One of the great successes of understanding complex systems.
- Navier-Stokes equations: micro-macro system evolution.
- The big three: Experiment + Theory + Simulations.
- Works for many very different 'fluids':
  - the atmosphere,
  - oceans,
  - blood,
  - the earth's mantle,
  - galaxies, ...
  - and ball bearings on lattices ...?**

For your consideration

# Limits to what's possible:

## Universality

- The property that the macroscopic aspects of a system do not depend sensitively on the system's details.
- Key figure: [Leo Kadanoff](#)
- Kadanoff's retrospective: "Innovations in Statistical Physics" [4]

## Examples:

- The Central Limit Theorem:

$$P(x; \mu, \sigma)dx = \frac{1}{\sqrt{2\pi\sigma}} e^{-(x-\mu)^2/2\sigma^2} dx.$$

- Navier Stokes equation for fluids.
- Nature of phase transitions in statistical mechanics.

## Freeman Dyson's of West's "Scale": [3]

The Key to Everything (nybooks.com)

"The astronomer Fang Lizhi published with his wife, Li Shuxian, a popular book, Creation of the Universe (1989), which includes the best explanation that I have seen of the paradox of order and disorder.

The explanation lies in the peculiar behavior of gravity in the physical world. On the balance sheet of energy accounting, gravitational energy is a deficit.

When you are close to a massive object, your gravitational energy is minus the amount of energy it would take to get away from the mass all the way to infinity.

When you walk up a hill on the earth, your gravitational energy is becoming less negative, but never gets up to zero.

Any object whose motions are dominated by gravity will have energy decreasing as temperature increases and energy increasing as temperature decreases."

# Dyson:

"As a consequence of the second law of thermodynamics, when energy flows from one such object to another, the hot object will grow hotter and the cold object will grow colder. That is why the sun grew hotter and the planets grew cooler as the solar system evolved.

In every situation where gravity is dominant, the second law causes local contrasts to increase together with entropy. This is true for astronomical objects like the sun, and also for large terrestrial objects such as thunderstorms and hurricanes.

The diversity of astronomical and terrestrial objects, including living creatures, tends to increase with time, in spite of the second law.

The evolution of natural ecologies and of human societies is a part of this pattern. West is evidently unaware of Fang and Li's insight."

Note: Unfortunately, Dyson takes the (disastrously wrong) biological scaling stuff as being sorted.

"Creation of the Universe"  
by Zhi and Xian (1989). [9]

The whole of thermodynamics starts from the existence of thermal equilibrium. For systems in which gravitation plays a decisive role, that sort of thermal equilibrium does not in fact exist. Both systems cannot be in a state of thermodynamic equilibrium, nor in some fixed state differing slightly from equilibrium, rather, they are in unstable states. It is not surprising that certain definitions in thermodynamics do not apply to such states.

**Formation of Structures**  
Let us look at another instructive example for cosmology. If in a container of gas, the distribution of the gas molecules is not uniform and has structure (as in Fig. 4.6(a)), then the direction of its evolution is for the distribution to become uniform and structureless (as in Fig. 4.6(b)). This is to say, the mode of evolution decided by the Second Law of Thermodynamics is

structured  $\rightarrow$  structureless  
non-uniform  $\rightarrow$  uniform

If the effect of gravitation among the gas molecules in this box of gas cannot be completely neglected, what will be the result? Suppose the distribution of the gas molecules is uniform at the beginning (as in Fig. 4.6(c)). When there is no gravitation, this is the equilibrium state, when there is gravitation, this equilibrium state becomes unstable. As soon as some local region acquires a slightly higher density through fluctuation, its gravitation becomes stronger, attracting more matter, and forming an even greater density. Likewise, if the density in some region is slightly lowered by fluctuation, its gravitation is weakened and more matter will sweep, forming a still lower density. In short, a small fluctuation will completely destroy the homogeneous state (as Fig. 4.6(d) & (e)). We therefore see that, in systems with strong gravitation, the direction of evolution is

structured  $\rightarrow$  structured  
uniform  $\rightarrow$  non-uniform

Throughout the universe, gravitation is dominant. Therefore, even if the initial universe is uniform and structureless, it will spontaneously generate a non-uniform and structured state. Clusters of galaxies of various scales are their formation in this process of inhomogeneity. At this point, we can answer the question posed at the beginning of this chapter as follows.
