net•work |'netwɜ:k|

- noun
- 1 an arrangement of intersecting horizontal and vertical lines.
 - a complex system of roads, railroads, or other transportation routes : a network of railroads.
 - 2 a group or system of interconnected people or things : a trade network.
 - a group of people who exchange information, contacts, and experience for professional or social purposes : a support network.
 - a group of broadcasting stations that connect for the simultaneous broadcast of a program : the introduction of a second TV network | [as adj.] network television.
 - a number of interconnected computers, machines, or operations : specialized computers that manage multiple outside connections to a network | a local cellular phone network.
 - a system of connected electrical conductors.

verb [trans.]
connect as or operate with a network : the stock exchanges have proven to be resourceful in networking these deals.
• link (machines, esp. computers) to operate interactively : [as adj.] (**networked**) networked workstations.
• [intrans.] [often as n.] (**networking**) interact with other people to exchange information and develop contacts, esp. to further one's career : the skills of networking, bargaining, and negotiation.

Ancestry:

Net and Work are venerable old words:

- ☿ 'Net' first used to mean spider web (King Ælfréd, 888).
- ☿ 'Work' appear to have long meant purposeful action.

- ☿ 'Network' = something built based on the idea of natural, flexible lattice or web.
- ☿ c.f., ironwork, stonework, fretwork.

The Science of Complex Systems Manifesto: [↗](#)

1. Systems are ubiquitous and systems matter.
2. Consequently, much of science is about understanding how pieces dynamically fit together.
3. 1700 to 2000 = Golden Age of Reductionism: Atoms!, sub-atomic particles, DNA, genes, people, ...
4. Understanding and creating systems (including new 'atoms') is the greater part of science and engineering.
5. [↗](#) Universality: systems with quantitatively different micro details exhibit qualitatively similar macro behavior.
6. Computing advances make the Science of Complex Systems possible:
 - 6.1 We can measure and record enormous amounts of data, research areas continue to transition from data scarce to data rich.
 - 6.2 We can simulate, model, and create complex systems in extraordinary detail.

Key Observation:

- ☿ Many complex systems can be viewed as complex networks of physical or abstract interactions.
- ☿ Opens door to mathematical and numerical analysis.
- ☿ Dominant approach of the first decade was of a theoretical-physics/stat-mechish flavor.
- ☿ Mindboggling amount of work published on complex networks since 1998 ...
- ☿ ... largely due to your typical theoretical physicist:

- ☿ Piranha physicus
- ☿ Hunt in packs.
- ☿ Feast on new and interesting ideas (see chaos, cellular automata, ...)
- ☿ See also: <http://ukcd.com/792/>

Nodes = A collection of entities which have properties that are somehow related to each other

- e.g., people, forks in rivers, proteins, webpages, organisms, ...

Links = Connections between nodes

- Links may be directed or undirected.
- Links may be binary or weighted.

Other spiffing words: vertices and edges.

So what passes for a complex network?

- Complex networks are **large** (in node number)
- Complex networks are **sparse** (low edge to node ratio)
- Complex networks are usually **dynamic** and **evolving**
- Complex networks can be social, economic, natural, informational, abstract, ...

Node degree = Number of links per node

- Notation: Node i 's degree = k_i .
- $k_i = 0, 1, 2, \dots$
- Notation: the average degree of a network = $\langle k \rangle$ (and sometimes z)
- Connection between number of edges m and average degree:
$$\langle k \rangle = \frac{2m}{N}$$
- Defn: \mathcal{N}_i = the set of i 's k_i neighbors

Adjacency matrix:

- We can represent a network by a matrix A with link weight a_{ij} for nodes i and j in entry (i, j) .

e.g.,

$$A = \begin{bmatrix} 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \end{bmatrix}$$

- For numerical work, we always use sparse matrices.
- For many real networks, A is a function of time.

Properties

2. Assortativity/3. Homophily:

- Social networks: Homophily = birds of a feather e.g., degree is standard property for sorting: measure degree-degree correlations.
- Assortative network: similar degree nodes connecting to each other. Often social: company directors, coauthors, actors.
- Disassortative network: high degree nodes connecting to low degree nodes. Often technological or biological: internet, WWW, protein interactions, neural networks, food webs.

Properties

1. degree distribution P_k

- P_k is the probability that a randomly selected node has degree k .
- k = node degree = number of connections.
- ex 1: Erdős-Rényi random networks have Poisson degree distributions:

$$P_k = e^{-\langle k \rangle} \frac{\langle k \rangle^k}{k!}$$

- ex 2: “Scale-free” networks: $P_k \propto k^{-\gamma} \Rightarrow$ ‘hubs’.
- link cost controls skew.
- hubs may facilitate or impede contagion.

Local socialness:

4. Clustering:

- Your friends tend to know each other.
- Two measures (explained on following slides):

1. Watts & Strogatz [112]

$$C_1 = \left\langle \frac{\sum_{j_1, j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i(k_i - 1)/2} \right\rangle_i$$

2. Newman [77]

$$C_2 = \frac{3 \times \text{\#triangles}}{\text{\#triples}}$$

A notable feature of large-scale networks:

- Graphical renderings are often just a big mess.

Typical hairball

- number of nodes $N = 500$
- number of edges $m = 1000$
- average degree $\langle k \rangle = 4$

And even when renderings somehow look good: “That is a very graphic analogy which aids understanding wonderfully while being, strictly speaking, wrong in every possible way” said Ponder [Stibbons] —*Making Money*, T. Pratchett.

- We need to extract digestible, meaningful aspects.

Properties

Note:

- Erdős-Rényi random networks are a mathematical construct.
- ‘Scale-free’ networks are growing networks that form according to a plausible mechanism.
- Randomness is out there, just not to the degree of a completely random network.
- “Becoming”: Stories = Characters + Time

Example network:

Calculation of C_1 :

- C_1 is the average fraction of pairs of neighbors who are connected.
- Fraction of pairs of neighbors who are connected is

$$\frac{\sum_{j_1, j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i(k_i - 1)/2}$$

where k_i is node i 's degree, and \mathcal{N}_i is the set of i 's neighbors.

- Averaging over all nodes, we have:

$$C_1 = \frac{1}{n} \sum_{i=1}^n \frac{\sum_{j_1, j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i(k_i - 1)/2} = \left\langle \frac{\sum_{j_1, j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i(k_i - 1)/2} \right\rangle_i$$

Triples and triangles

Example network:

Triangles:

Triples:

- Nodes $i_1, i_2,$ and i_3 form a **triple** around i_1 if i_1 is connected to i_2 and i_3 .
- Nodes $i_1, i_2,$ and i_3 form a **triangle** if each pair of nodes is connected
- The definition $C_2 = \frac{3 \times \# \text{triangles}}{\# \text{triples}}$ measures the fraction of **closed triples**
- The '3' appears because for each triangle, we have 3 closed triples.
- Social Network Analysis (SNA): fraction of **transitive triples**.

Clustering:

Sneaky counting for undirected, unweighted networks:

- If the path $i-j-l$ exists then $a_{ij}a_{j\ell} = 1$.
- Otherwise, $a_{ij}a_{j\ell} = 0$.
- We want $i \neq \ell$ for good triples.
- In general, a path of n edges between nodes i_1 and i_n travelling through nodes i_2, i_3, \dots, i_{n-1} exists $\Leftrightarrow a_{i_1 i_2} a_{i_2 i_3} a_{i_3 i_4} \dots a_{i_{n-2} i_{n-1}} a_{i_{n-1} i_n} = 1$.

$$\# \text{triples} = \frac{1}{2} \left(\sum_{i=1}^N \sum_{\ell=1}^N [A^2]_{i\ell} - \text{Tr} A^2 \right)$$

$$\# \text{triangles} = \frac{1}{6} \text{Tr} A^3$$

9. network distances:

- network diameter** d_{\max} : Maximum shortest path length between any two nodes.
- closeness** $d_{cl} = [\sum_{ij} d_{ij}^{-1} / \binom{n}{2}]^{-1}$: Average 'distance' between any two nodes.
- Closeness handles disconnected networks ($d_{ij} = \infty$)
- $d_{cl} = \infty$ only when all nodes are isolated.
- Closeness perhaps compresses too much into one number

Interconnected networks and robustness (two for one deal):

“Catastrophic cascade of failures in interdependent networks” [21]. Buldyrev et al., Nature 2010.

Figure 1. Modelling a blackout in Italy. Illustration of an iterative process of a cascade of failures using real-world data from a power network located on the map of Italy and an Internet network (shaded above the map) that were simplified in an electrical blackout that occurred in Italy in September 2003. The networks are drawn using the real geographical locations and every Internet server is connected to the geographical nearest power station. a. One power station is removed (red node on map) from the power network and as a result the Internet nodes depending on it are removed from the Internet network (red nodes above the map). The nodes that will be disconnected from the giant cluster (a cluster that spans the entire network) at the next step are marked in green. b. Additional nodes that were disconnected from the Internet communication network giant component are removed (red nodes above map). As a result the power station depending on them are removed from the power network (red nodes on map). Again, the nodes that will be disconnected from the giant cluster at the next step are marked in green. c. Additional nodes that were disconnected from the giant component of the power network are removed (red nodes on map) as well as the nodes in the Internet network that depend on them (red nodes above map).

Branching networks are useful things:

- Fundamental to material **supply and collection**
- Supply:** From one source to many sinks in 2- or 3-d.
- Collection:** From many sources to one sink in 2- or 3-d.
- Typically observe hierarchical, recursive self-similar structure

Examples:

- River networks
- Cardiovascular networks
- Plants
- Evolutionary trees
- Organizations (only in theory ...)

FIG. 8.—An ideal diagrammatic summary of the development of a drainage system (area for purposes of comparison only). The first four parts show extension, then 1, initiation; 2, elongation; 3, elaboration and 4, maximum extension. Parts 5 and 6 represent atrophy during integration.

The sequential stages recognized in the evolution of a drainage system are “extension” and “integration”; the first, a stage of increasing complexity; the second, of simplification.

‘Laws’

Hack’s law (1957) [50]:

$$l \propto a^h$$

reportedly $0.5 < h < 0.7$

Scaling of main stream length with basin size:

$$l \propto L^d$$

reportedly $1.0 < d < 1.1$

Basin allometry:

$$L_{\parallel} \propto a^{h/d} \equiv a^{1/D}$$

$D < 2 \rightarrow$ basins elongate.

There are a few more 'laws': [31]

Relation:	Name or description:
$T_k = T_1 (R_T)^{k-1}$	Tokunaga's law
$\ell \sim L^d$	self-affinity of single channels
$n_\omega / n_{\omega+1} = R_n$	Horton's law of stream numbers
$\ell_{\omega+1} / \ell_\omega = R_\ell$	Horton's law of main stream lengths
$\bar{a}_{\omega+1} / \bar{a}_\omega = R_a$	Horton's law of main stream areas
$\bar{s}_{\omega+1} / \bar{s}_\omega = R_s$	Horton's law of stream segment lengths
$L_\perp \sim L^H$	scaling of basin widths
$P(a) \sim a^{-\tau}$	probability of basin areas
$P(\ell) \sim \ell^{-\gamma}$	probability of stream lengths
$\ell \sim a^h$	Hack's law
$a \sim L^D$	scaling of basin areas
$\Lambda \sim a^\beta$	Langbein's law
$\lambda \sim L^\varphi$	variation of Langbein's law

Horton's laws

Self-similarity of river networks

First quantified by Horton (1945) [53], expanded by Schumm (1956) [88]

Three laws:

Horton's law of stream numbers:

$$n_\omega / n_{\omega+1} = R_n > 1$$

Horton's law of stream lengths:

$$\ell_{\omega+1} / \ell_\omega = R_\ell > 1$$

Horton's law of basin areas:

$$\bar{a}_{\omega+1} / \bar{a}_\omega = R_a > 1$$

Network Architecture

Tokunaga's law [101, 102, 103]

Property 1: Scale independence—depends only on difference between orders:

$$T_{\mu,\nu} = T_{\mu-\nu}$$

Property 2: Number of side streams grows exponentially with difference in orders:

$$T_{\mu,\nu} = T_1 (R_T)^{\mu-\nu-1}$$

We usually write Tokunaga's law as:

$$T_k = T_1 (R_T)^{k-1} \text{ where } R_T \approx 2$$

Growing networks: [117]

☿ Top: $\alpha = 0.66, \beta = 0.38$; Bottom: $\alpha = 0.66, \beta = 0.70$

Single source optimal supply

An immensely controversial issue ...

- ☿ The form of natural branching networks: Random, optimal, or some combination? [55, 113, 7, 33, 27]
- ☿ River networks, blood networks, trees, ...

Two observations:

- ☿ Self-similar networks appear everywhere in nature for single source supply/single sink collection.
- ☿ Real networks differ in **details of scaling** but reasonably agree in **scaling relations**.

Optimization—Murray's law ☞

☿ Murray's law (1926) connects branch radii at forks: [72, 71, 73, 59, 100]

$$r_{\text{parent}}^3 = r_{\text{offspring1}}^3 + r_{\text{offspring2}}^3$$

where r_{parent} = radius of 'parent' branch, and $r_{\text{offspring1}}$ and $r_{\text{offspring2}}$ are radii of the two 'offspring' sub-branches.

- ☿ Holds up well for outer branchings of blood networks [90].
- ☿ Also found to hold for trees [73, 66] when xylem is not a supporting structure [67].
- ☿ See D'Arcy Thompson's "On Growth and Form" for background and general inspiration [99, 100].

Hack's law

- Volume of water in river network can be calculated by adding up basin areas
- Flows sum in such a way that

$$V_{net} = \sum_{\text{all pixels}} a_{\text{pixel } i}$$

- Hack's law again:

$$l \sim a^h$$

- Can argue

$$V_{net} \propto V_{\text{basin}}^{1+h} = a_{\text{basin}}^{1+h}$$

where h is Hack's exponent.

- ∴ minimal volume calculations gives

$$h = 1/2$$

Real data:

Banavar et al.'s approach [7] is okay because ρ really is constant.

The irony: shows optimal basins are isometric

Optimal Hack's law: $\ell \sim a^h$ with $h = 1/2$

(Zzzzz)

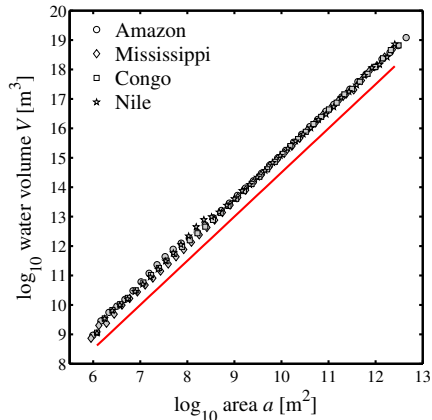

Figure 2 Allometric scaling in river networks. Double logarithmic plot of $C = \sum_i A_i$ versus A for three river networks characterized by different climates, geology and geographic locations (Dry Fork, West Virginia, 586 km², digital terrain map (DTM) size 30 × 30 m²; Island Creek, Idaho, 260 km², DTM size 30 × 30 m²; Tiroso, Italy, 2,024 km², DTM size 237 × 237 m²). The experimental points are obtained by binning total contributing areas, and computing the ensemble average of the sum of the linear areas for each sub-basin within the binned interval. The figure uses pixel units in which the smallest area element is assigned a unit value. Also plotted is the predicted scaling relationship with slope 3/2. The inset shows the raw data from the Tiroso basin before any binning has been done.

Even better—prefactors match up:

"Optimal design of spatial distribution networks"
Gastner and Newman,
Phys. Rev. E, **74**, 016117, 2006. [40]

- Approximately optimal location of 5000 facilities. Based on 2000 Census data.
- Simulated annealing + Voronoi tessellation.

Optimal source allocation

- Optimal facility density ρ_{fac} vs. population density ρ_{pop} .
- Fit is $\rho_{fac} \propto \rho_{pop}^{0.66}$ with $r^2 = 0.94$.
- Looking good for a 2/3 power ...

Deriving the optimal source distribution:

- Basic idea:** Minimize the average distance from a random individual to the nearest facility. [40]
- Assume given a fixed population density ρ_{pop} defined on a spatial region Ω .

- Formally, we want to find the locations of n sources $\{\vec{x}_1, \dots, \vec{x}_n\}$ that minimizes the **cost function**

$$F(\{\vec{x}_1, \dots, \vec{x}_n\}) = \int_{\Omega} \rho_{pop}(\vec{x}) \min_i \|\vec{x} - \vec{x}_i\| d\vec{x}.$$

- Also known as the p-median problem, and connected to cluster analysis.
- Not easy ...in fact this one is an NP-hard problem. [40]
- Approximate solution originally due to Gusein-Zade [49].

Global redistribution networks

One more thing:

- How do we supply these facilities?
- How do we best redistribute mail? People?
- How do we get beer to the pubs?
- Gastner and Newman model: cost is a function of basic maintenance and travel time:

$$C_{maint} + \gamma C_{travel}$$

- Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance ℓ_{ij} and number of legs to journey:

$$(1 - \delta)\ell_{ij} + \delta(\#\text{hops}).$$

- When $\delta = 1$, only number of hops matters.

Global redistribution networks

From Gastner and Newman (2006) [40]

Public versus private facilities

Beyond minimizing distances:

- "Scaling laws between population and facility densities" by Um *et al.*, Proc. Natl. Acad. Sci., 2009. [104]

- Um *et al.* find empirically and argue theoretically that the connection between facility and population density

$$\rho_{fac} \propto \rho_{pop}^{\alpha}$$

does not universally hold with $\alpha = 2/3$.

- Two idealized limiting classes:

- For-profit, commercial facilities: $\alpha = 1$;
- Pro-social, public facilities: $\alpha = 2/3$.

- Um *et al.* investigate facility locations in the United States and South Korea.

Public versus private facilities: evidence

- Left plot: ambulatory hospitals in the U.S.
- Right plot: public schools in the U.S.
- Note: break in scaling for public schools. Transition from $\alpha \approx 2/3$ to $\alpha = 1$ around $\rho_{pop} \approx 100$.

- So for large random networks ($N \rightarrow \infty$), clustering drops to zero.
- Key structural feature of random networks is that they locally look like pure branching networks
- No small loops.

Degree distribution:

- Recall P_k = probability that a randomly selected node has degree k .
- Consider method 1 for constructing random networks: each possible link is realized with probability p .
- Now consider one node: there are ' $N - 1$ choose k ' ways the node can be connected to k of the other $N - 1$ nodes.
- Each connection occurs with probability p , each non-connection with probability $(1 - p)$.
- Therefore have a binomial distribution

$$P(k; p, N) = \binom{N-1}{k} p^k (1-p)^{N-1-k}$$

Limiting form of $P(k; p, N)$:

- Our degree distribution: $P(k; p, N) = \binom{N-1}{k} p^k (1-p)^{N-1-k}$
- What happens as $N \rightarrow \infty$?
- We must end up with the normal distribution right?
- If p is fixed, then we would end up with a Gaussian with average degree $\langle k \rangle \approx pN \rightarrow \infty$.
- But we want to keep $\langle k \rangle$ fixed ...
- So examine limit of $P(k; p, N)$ when $p \rightarrow 0$ and $N \rightarrow \infty$ with $\langle k \rangle = p(N - 1) = \text{constant}$.

$$P(k; p, N) \approx \frac{\langle k \rangle^k}{k!} \left(1 - \frac{\langle k \rangle}{N-1}\right)^{N-1-k} \rightarrow \frac{\langle k \rangle^k}{k!} e^{-\langle k \rangle}$$

- This is a Poisson distribution with mean $\langle k \rangle$.

The edge-degree distribution:

- The degree distribution P_k is fundamental for our description of many complex networks
- Again: P_k is the degree of **randomly chosen node**.
- A second very important distribution arises from **choosing randomly on edges** rather than on nodes.
- Define Q_k to be the probability the node at a **random end of a randomly chosen edge** has degree k .
- Now choosing nodes based on their degree (i.e., size):

$$Q_k \propto k P_k$$

- Normalized form:

$$Q_k = \frac{k P_k}{\sum_{k'=0}^{\infty} k' P_{k'}} = \frac{k P_k}{\langle k \rangle}$$

- Big deal:** Rich-get-richer mechanism is built into this selection process.

The edge-degree distribution:

For networks, Q_k is also the probability that a friend (neighbor) of a random node has k friends.

Useful variant on Q_k :

R_k = probability that a friend of a random node has k other friends.

$$R_k = \frac{(k+1)P_{k+1}}{\sum_{k'=0} (k'+1)P_{k'+1}} = \frac{(k+1)P_{k+1}}{\langle k \rangle}$$

Equivalent to friend having degree $k+1$.

Natural question: what's the expected number of other friends that one friend has?

"Generalized friendship paradox in complex networks: The case of scientific collaboration"

Eom and Jo, Nature Scientific Reports, 4, 4603, 2014. [35]

Your friends really are monsters #winners:¹

Go on, hurt me: Friends have more coauthors, citations, and publications.

Other horrific studies: your connections on Twitter have more followers than you, are happier than you [17], more sexual partners than you, ...

The hope: Maybe they have more enemies and diseases too.

Research possibility: The Frenemy Paradox.

¹Some press [here](#) [MIT Tech Review].

Spreading on Random Networks

For random networks, we know local structure is pure branching.

Successful spreading is :: contingent on single edges infecting nodes.

Success

Failure:

Focus on binary case with edges and nodes either infected or not.

First big question: for a given network and contagion process, can global spreading from a single seed occur?

Probability of randomly selecting a node of degree k by choosing from nodes: $P_1 = 3/7, P_2 = 2/7, P_3 = 1/7, P_6 = 1/7$.

Probability of landing on a node of degree k after randomly selecting an edge and then randomly choosing one direction to travel: $Q_1 = 3/16, Q_2 = 4/16, Q_3 = 3/16, Q_6 = 6/16$.

Probability of finding # outgoing edges = k after randomly selecting an edge and then randomly choosing one direction to travel: $R_0 = 3/16, R_1 = 4/16, R_2 = 3/16, R_5 = 6/16$.

Two reasons why this matters

Reason #1:

Average # friends of friends per node is

$$\langle k_2 \rangle = \langle k \rangle \times \langle k \rangle_R = \langle k \rangle \frac{1}{\langle k \rangle} (\langle k^2 \rangle - \langle k \rangle) = \langle k^2 \rangle - \langle k \rangle.$$

Key: Average depends on the 1st and 2nd moments of P_k and not just the 1st moment.

Three peculiarities:

- We might guess $\langle k_2 \rangle = \langle k \rangle \langle k \rangle$ but it's actually $\langle k(k-1) \rangle$.
- If P_k has a large second moment, then $\langle k_2 \rangle$ will be big. (e.g., in the case of a power-law distribution)
- Your friends really are different from you ... [37, 76]
- See also: class size paradoxes (nod to: Gelman)

Global spreading condition

We need to find: [30]

R = the average # of infected edges that one random infected edge brings about.

Call R the gain ratio.

Define B_{k1} as the probability that a node of degree k is infected by a single infected edge.

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot \underbrace{(k-1)}_{\substack{\text{\# outgoing} \\ \text{infected} \\ \text{edges}}} \cdot \underbrace{B_{k1}}_{\substack{\text{Prob. of} \\ \text{infection}}} + \sum_{k=0}^{\infty} \frac{\widehat{kP_k}}{\langle k \rangle} \cdot \underbrace{0}_{\substack{\text{\# outgoing} \\ \text{infected} \\ \text{edges}}} \cdot \underbrace{(1-B_{k1})}_{\substack{\text{Prob. of} \\ \text{no infection}}}$$

Global spreading condition

Our global spreading condition is then:

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1} > 1.$$

Case 1-Rampant spreading: If $B_{k1} = 1$ then

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) = \frac{\langle k(k-1) \rangle}{\langle k \rangle} > 1.$$

Good: This is just our giant component condition again.

Global spreading condition

Case 2—Simple disease-like: If $B_{k1} = \beta < 1$ then

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot \beta > 1.$$

A fraction $(1-\beta)$ of edges do not transmit infection.

Analogous phase transition to giant component case but critical value of $\langle k \rangle$ is increased.

Aka bond percolation.

Resulting degree distribution \tilde{P}_k :

$$\tilde{P}_k = \beta^k \sum_{i=k}^{\infty} \binom{i}{k} (1-\beta)^{i-k} P_i.$$

Random directed networks:

So far, we've largely studied networks with undirected, unweighted edges.

Now consider directed, unweighted edges.

Nodes have k_i and k_o incoming and outgoing edges, otherwise random.

Network defined by joint in- and out-degree distribution: P_{k_i, k_o}

Normalization: $\sum_{k_i=0}^{\infty} \sum_{k_o=0}^{\infty} P_{k_i, k_o} = 1$

Marginal in-degree and out-degree distributions:

$$P_{k_i} = \sum_{k_o=0}^{\infty} P_{k_i, k_o} \text{ and } P_{k_o} = \sum_{k_i=0}^{\infty} P_{k_i, k_o}$$

Required balance:

$$\langle k_i \rangle = \sum_{k_i=0}^{\infty} \sum_{k_o=0}^{\infty} k_i P_{k_i, k_o} = \sum_{k_i=0}^{\infty} \sum_{k_o=0}^{\infty} k_o P_{k_i, k_o} = \langle k_o \rangle$$

Directed network structure:

From Boguñá and Serano. [15]

- GWCC = Giant Weakly Connected Component (directions removed);
- GIN = Giant In-Component;
- GOUT = Giant Out-Component;
- GSCC = Giant Strongly Connected Component;
- DC = Disconnected Components (finite).

When moving through a family of increasingly connected directed random networks, GWCC usually appears before GIN, GOUT, and GSCC which tend to appear together. [80, 15]

Observation:

- Directed and undirected random networks are separate families ...
- ...and analyses are also disjoint.
- Need to examine a larger family of random networks with mixed directed and undirected edges.

- Consider nodes with three types of edges:
 1. k_u undirected edges,
 2. k_i incoming directed edges,
 3. k_o outgoing directed edges.

- Define a node by generalized degree:

$$\vec{k} = [k_u \ k_i \ k_o]^T.$$

Correlations:

- Now add correlations (two point or Markovian) \square :
 1. $P^{(u)}(\vec{k} | \vec{k}')$ = probability that an undirected edge leaving a degree \vec{k}' nodes arrives at a degree \vec{k} node.
 2. $P^{(i)}(\vec{k} | \vec{k}')$ = probability that an edge leaving a degree \vec{k}' nodes arrives at a degree \vec{k} node is an in-directed edge relative to the destination node.
 3. $P^{(o)}(\vec{k} | \vec{k}')$ = probability that an edge leaving a degree \vec{k}' nodes arrives at a degree \vec{k} node is an out-directed edge relative to the destination node.
- Now require more refined (detailed) balance.
- Conditional probabilities cannot be arbitrary.
 1. $P^{(u)}(\vec{k} | \vec{k}')$ must be related to $P^{(u)}(\vec{k}', | \vec{k})$.
 2. $P^{(o)}(\vec{k} | \vec{k}')$ and $P^{(i)}(\vec{k} | \vec{k}')$ must be connected.

Correlations—Undirected edge balance:

- Randomly choose an edge, and randomly choose one end.
- Say we find a degree \vec{k} node at this end, and a degree \vec{k}' node at the other end.
- Define probability this happens as $P^{(u)}(\vec{k}, \vec{k}')$.
- Observe we must have $P^{(u)}(\vec{k}, \vec{k}') = P^{(u)}(\vec{k}', \vec{k})$.

- Conditional probability connection:

$$P^{(u)}(\vec{k}, \vec{k}') = P^{(u)}(\vec{k} | \vec{k}') \frac{k'_u P(\vec{k}')}{\langle k'_u \rangle}$$

$$P^{(u)}(\vec{k}', \vec{k}) = P^{(u)}(\vec{k}' | \vec{k}) \frac{k_u P(\vec{k})}{\langle k_u \rangle}$$

Correlations—Directed edge balance:

- The quantities

$$\frac{k_o P(\vec{k})}{\langle k_o \rangle} \text{ and } \frac{k_i P(\vec{k})}{\langle k_i \rangle}$$

give the probabilities that in starting at a random end of a randomly selected edge, we begin at a degree \vec{k} node and then find ourselves travelling:

1. along an outgoing edge, or
2. against the direction of an incoming edge.

- We therefore have

$$P^{(dir)}(\vec{k}, \vec{k}') = P^{(i)}(\vec{k} | \vec{k}') \frac{k'_o P(\vec{k}')}{\langle k'_o \rangle} = P^{(o)}(\vec{k}' | \vec{k}) \frac{k_i P(\vec{k})}{\langle k_i \rangle}.$$

- Note that $P^{(dir)}(\vec{k}, \vec{k}')$ and $P^{(dir)}(\vec{k}', \vec{k})$ are in general not related if $\vec{k} \neq \vec{k}'$.

Summary of contagion conditions for uncorrelated networks:

- I. Undirected, Uncorrelated— $f(d+1) = \mathbf{f}(d)$:

$$\mathbf{R} = \sum_{k_u} P^{(u)}(k_u | *) \bullet (k_u - 1) \bullet B_{k_u, *}$$

- II. Directed, Uncorrelated— $f(d+1) = \mathbf{f}(d)$:

$$\mathbf{R} = \sum_{k_i, k_o} P^{(i)}(k_i, k_o | *) \bullet k_o \bullet B_{k_i, *}$$

- III. Mixed Directed and Undirected, Uncorrelated—

$$\begin{bmatrix} f^{(u)}(d+1) \\ f^{(o)}(d+1) \end{bmatrix} = \mathbf{R} \begin{bmatrix} f^{(u)}(d) \\ f^{(o)}(d) \end{bmatrix}$$

$$\mathbf{R} = \sum_{\vec{k}} \begin{bmatrix} P^{(u)}(\vec{k} | *) \bullet (k_u - 1) & P^{(i)}(\vec{k} | *) \bullet k_u \\ P^{(u)}(\vec{k} | *) \bullet k_o & P^{(i)}(\vec{k} | *) \bullet k_o \end{bmatrix} \bullet B_{k_u k_i, *}$$

Summary of contagion conditions for correlated networks:

- IV. Undirected, Correlated— $f_{k_u}(d+1) = \sum_{k'_u} R_{k_u k'_u} f_{k'_u}(d)$

$$R_{k_u k'_u} = P^{(u)}(k_u | k'_u) \bullet (k_u - 1) \bullet B_{k_u k'_u}$$

- V. Directed, Correlated— $f_{k_i k_o}(d+1) = \sum_{k'_i, k'_o} R_{k_i k_o k'_i k'_o} f_{k'_i k'_o}(d)$

$$R_{k_i k_o k'_i k'_o} = P^{(i)}(k_i, k_o | k'_i, k'_o) \bullet k_o \bullet B_{k_i k_o k'_i k'_o}$$

- VI. Mixed Directed and Undirected, Correlated—

$$\begin{bmatrix} f_{\vec{k}}^{(u)}(d+1) \\ f_{\vec{k}}^{(o)}(d+1) \end{bmatrix} = \sum_{\vec{k}'} \mathbf{R}_{\vec{k} \vec{k}'} \begin{bmatrix} f_{\vec{k}'}^{(u)}(d) \\ f_{\vec{k}'}^{(o)}(d) \end{bmatrix}$$

$$\mathbf{R}_{\vec{k} \vec{k}'} = \begin{bmatrix} P^{(u)}(\vec{k} | \vec{k}') \bullet (k_u - 1) & P^{(i)}(\vec{k} | \vec{k}') \bullet k_u \\ P^{(u)}(\vec{k} | \vec{k}') \bullet k_o & P^{(i)}(\vec{k} | \vec{k}') \bullet k_o \end{bmatrix} \bullet B_{\vec{k} \vec{k}'}$$

Full generalization:

$$f_{\vec{\alpha}}(d+1) = \sum_{\vec{\alpha}'} R_{\vec{\alpha} \vec{\alpha}'} f_{\vec{\alpha}'}(d)$$

$R_{\vec{\alpha} \vec{\alpha}'}$ is the gain ratio matrix and has the form:

$$R_{\vec{\alpha} \vec{\alpha}'} = P_{\vec{\alpha} \vec{\alpha}'} \bullet k_{\vec{\alpha} \vec{\alpha}'} \bullet B_{\vec{\alpha} \vec{\alpha}'}$$

- $P_{\vec{\alpha} \vec{\alpha}'}$ = conditional probability that a type λ' edge emanating from a type ν' node leads to a type ν node.
- $k_{\vec{\alpha} \vec{\alpha}'}$ = potential number of newly infected edges of type λ emanating from nodes of type ν .
- $B_{\vec{\alpha} \vec{\alpha}'}$ = probability that a type ν node is eventually infected by a single infected type λ' link arriving from a neighboring node of type ν' .
- Generalized contagion condition:

$$\max |\mu| : \mu \in \sigma(\mathbf{R}) > 1$$

Some claims for social networks:

- Social networks yes, but groups, groups, groups
- Sufficiently large social groups are:
 1. Fandoms.
 2. Pyramid Schemes,
 3. Or both.
- Homo narrativus: Storytellers, believers, spreaders.
- Stories ~ Characters + Time.
- Characters are shortcuts to stories.

For novel diseases:

1. Can we predict the size of an epidemic?
2. How important is the reproduction number R_0 ?

R_0 approximately same for all of the following:

- 1918-19 "Spanish Flu" ~ 75,000,000 world-wide, 500,000 deaths in US.
- 1957-58 "Asian Flu" ~ 2,000,000 world-wide, 70,000 deaths in US.
- 1968-69 "Hong Kong Flu" ~ 1,000,000 world-wide, 34,000 deaths in US.
- 2003 "SARS Epidemic" ~ 800 deaths world-wide.

Improving simple models

Idea for social networks: incorporate identity

Identity is formed from attributes such as:

- Geographic location
- Type of employment
- Age
- Recreational activities

Groups are crucial ...

- formed by people with at least one similar attribute
- Attributes \leftrightarrow Contexts \leftrightarrow Interactions \leftrightarrow Networks. [110]

Generalized context space

Example model output: size distributions

- Flat distributions are possible for certain ξ and P .
- Different R_0 's may produce similar distributions
- Same epidemic sizes may arise from different R_0 's

Model output—resurgence

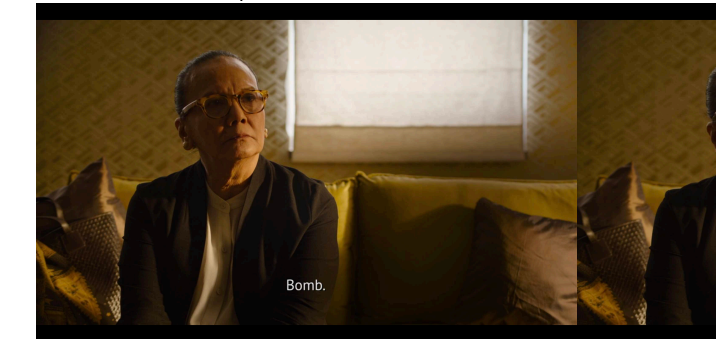

Journal entry, 2020/02/21:

Twitter DMs to Sam Scarpino:

- Okay: The scientists studying pandemics need to be able to present some kind set of numbers that show how bad things are. The whole R_0 disaster has been waiting to happen because people have been ... lazily having fun with math models? Unconcerned about how to communicate vital scientific information? Stupid? I don't know. Maybe a radar plot visualization. I don't know.
- "When these three boundaries are crossed, we are in trouble"
- Measles has an R_0 of 20. We should all have it. Of course, there's no f**king time scale for R_0 so we don't know when that happens.

For example:

Essential Extract of a Growth Model:

Random Competitive Replication (RCR):

- Start with 1 elephant (or element) of a particular flavor at $t = 1$
 - At time $t = 2, 3, 4, \dots$, add a new elephant in one of two ways:
 - With probability ρ , create a new elephant with a new flavor
= Mutation/Innovation
 - With probability $1 - \rho$, randomly choose from all existing elephants, and make a copy.
= Replication/Imitation
- Elephants of the same flavor form a group

- Micro-to-Macro story with ρ and γ measurable.

$$\gamma = \frac{(2-\rho)}{(1-\rho)} = 1 + \frac{1}{(1-\rho)}$$

- Observe $2 < \gamma < \infty$ for $0 < \rho < 1$.
- For $\rho \approx 0$ (low innovation rate): $\gamma \approx 2$
- 'Wild' power-law size distribution of group sizes, bordering on 'infinite' mean.
- For $\rho \approx 1$ (high innovation rate): $\gamma \approx \infty$
- All elephants have different flavors.
- Upshot: Tunable mechanism producing a family of universality classes.

- Simon (1961): "Reply to Dr. Mandelbrot's post scriptum" [94]

Scale-free networks

- Real networks with power-law degree distributions became known as **scale-free** networks.
- Scale-free refers specifically to the **degree distribution** having a **power-law decay** in its tail:

$$P_k \sim k^{-\gamma} \text{ for 'large' } k$$

- One of the seminal works in complex networks:

"Emergence of scaling in random networks" [8]
Barabási and Albert,
Science, **286**, 509–511, 1999. [8]

Times cited: ~ 43,853 [8] (as of May 19, 2023)

- Somewhat misleading nomenclature ...

Social Contagion

Some important models:

- Tipping models—Schelling (1971) [85, 86, 87]
 - Simulation on checker boards
 - Idea of thresholds
 - Polygon-themed online visualization. (Includes optional diversity-seeking proclivity.) [8]
- Threshold models—Granovetter (1978) [47]
- Herding models—Bikhchandani, Hirschleifer, Welch (1992) [10, 11]
 - Social learning theory, Informational cascades,...

Social contagion models

Thresholds

- Basic idea: individuals adopt a behavior when a **certain fraction of others** have adopted
- 'Others' may be everyone in a population, an individual's close friends, any reference group.
- Response can be probabilistic or deterministic.
- Individual thresholds can vary
- Assumption: order of others' adoption does not matter... (**unrealistic**).
- Assumption: level of influence per person is uniform (**unrealistic**).

Social Contagion

Some possible origins of thresholds:

- Inherent, evolution-devised inclination to coordinate, to conform, to imitate. [9]
- Lack of information:** impute the worth of a good or behavior based on degree of adoption (social proof)
- Economics: Network effects or network externalities**
 - Externalities = Effects on others not directly involved in a transaction
 - Examples: telephones, fax machine, TikTok, operating systems
 - An individual's utility increases with the adoption level among peers and the population in general

Threshold models—Nutshell

Implications for collective action theory:

- Collective uniformity \nRightarrow individual uniformity
- Small individual changes \Rightarrow large global changes
- The stories/dynamics of complex systems are conceptually inaccessible for individual-centric narratives.
- System stories live in left null space of our stories—we can't even see them.
- But we happily impose simplistic, individual-centric stories—we can't help ourselves ↗.

$$\Omega_{crit} \subset \Omega_{trig}; \Omega_{crit} \subset \Omega_{final}; \text{ and } \Omega_{trig}, \Omega_{final} \subset \Omega.$$

Cascade condition

Back to following a link:

- A randomly chosen link, traversed in a random direction, leads to a degree k node with probability $\propto kP_k$.
- Follows from there being k ways to connect to a node with degree k .
- Normalization:

$$\sum_{k=0}^{\infty} kP_k = \langle k \rangle$$

So

$$P(\text{linked node has degree } k) = \frac{kP_k}{\langle k \rangle}$$

Cascade condition

So... for random networks with fixed degree distributions, cascades take off when:

$$\sum_{k=1}^{\infty} (k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

- β_k = probability a degree k node is vulnerable.
- P_k = probability a node has degree k .

Expected size of spread

Pleasantness:

- Taking off from a single seed story is about **expansion** away from a node.
- Extent of spreading story is about **contraction** at a node.

Cascade condition

Next: Vulnerability of linked node

- Linked node is **vulnerable** with probability

$$\beta_k = \int_{\phi'_* = 0}^{1/k} f(\phi'_*) d\phi'_*$$

- If linked node is **vulnerable**, it produces $k-1$ new outgoing active links
- If linked node is **not vulnerable**, it produces **no** active links.

Cascade condition

Two special cases:

- (1) Simple disease-like spreading succeeds: $\beta_k = \beta$

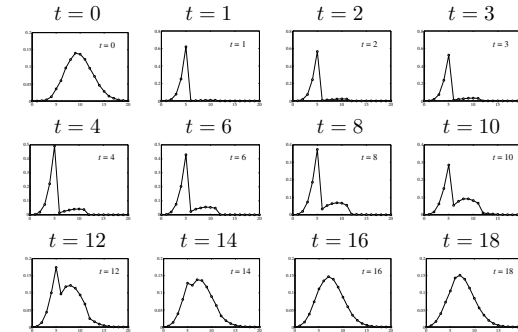

$$\beta \cdot \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

- (2) Giant component exists: $\beta = 1$

$$1 \cdot \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

Cascade condition

Putting things together:

- Expected number of active edges produced by an active edge:

$$R = \left[\sum_{k=1}^{\infty} \underbrace{(k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle}}_{\text{success}} + \underbrace{0 \cdot (1-\beta_k) \cdot \frac{kP_k}{\langle k \rangle}}_{\text{failure}} \right]$$

$$= \sum_{k=1}^{\infty} (k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle}$$

Extensions

“Threshold Models of Social Influence”
Watts and Dodds,
The Oxford Handbook of Analytical
Sociology, **63**, 475–497, 2009. [109]

- Assumption of sparse interactions is good
- Degree distribution is (generally) key to a network's function
- Still, random networks don't represent all networks
- Major element missing: **group structure**

Group structure—Ramified random networks

p = intergroup connection probability
 q = intragroup connection probability.

Generalized affiliation model networks with triadic closure

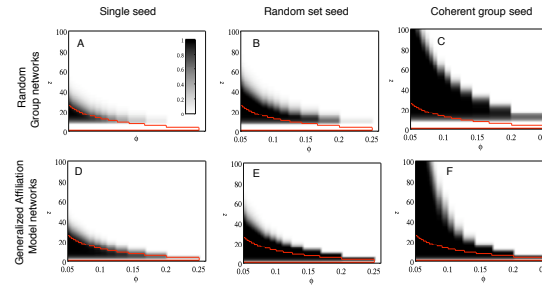

- Connect nodes with probability $\propto e^{-\alpha d}$ where α = homophily parameter and d = distance between nodes (height of lowest common ancestor)
- τ_1 = intergroup probability of friend-of-friend connection
- τ_2 = intragroup probability of friend-of-friend connection

Cascade windows for group-based networks

Multiplier effect for group-based networks:

- Multiplier almost always below 1.

Assortativity in group-based networks

- The most connected nodes aren't always the most 'influential.'
- Degree assortativity** is the reason.

Social contagion

“Without followers, evil cannot spread.” –Leonard Nimoy

Summary

- 'Influential vulnerables' are key to spread.
- Early adopters are mostly vulnerables.
- Vulnerable nodes important but not necessary.
- Groups may greatly facilitate spread.
- Seems that cascade condition is a global one.
- Most extreme/unexpected cascades occur in highly connected networks
- 'Influentials' are posterior constructs.
- Many potential influentials exist.

Social contagion

Implications

- Focus on the influential vulnerables.
- Create entities that can be transmitted successfully through many individuals rather than broadcast from one 'influential.'
- Only simple ideas can spread by word-of-mouth. (Idea of opinion leaders spreads well...)
- Want enough individuals who will adopt and display.
- Displaying can be passive = free (yo-yo's, fashion), or active = harder to achieve (political messages; even so: buttons and hats).
- Entities can be novel or designed to combine with others, e.g. block another one.

“Flavor network and the principles of food pairing”
Ahn et al.,
Nature Scientific Reports, **1**, 196, 2011. [1]

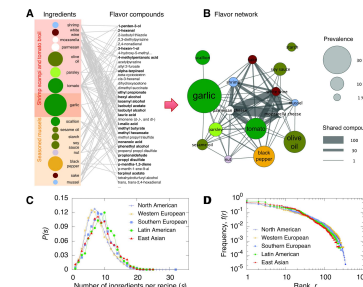

Figure 1 | Flavor network. (A) The ingredients contained in seven recipes (left column), together with the flavor compounds that are known to be present in the ingredients (right column). Each flavor compound is linked to the ingredients that contain it, forming a bipartite network. Some compounds (shown in boldface) are shared by multiple ingredients. (B) The project the bipartite compound-ingredient network into the ingredient space, so entities in the flavor network whose nodes are ingredients. Bolded lines at least are flavor compounds. The thickness of links represents the number of times a given compound-ingredient pair occurs in the recipe. (C) The number of ingredients per recipe, across the 100 recipes in the dataset. (D) The frequency rank of ingredients across the 100 recipes (see an approximately similar distribution across the dataset).

“Flavor network and the principles of food pairing”
Ahn et al.,
Nature Scientific Reports, **1**, 196, 2011. [1]

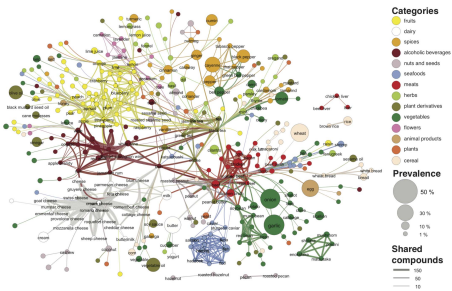

Figure 2: The backbone of the flavor network. Each node denotes an ingredient, the node color indicates food category, and node size reflects the ingredient prevalence in recipes. Two ingredients are connected if they share a significant number of flavor compounds, link thickness representing the number of shared compounds between the two ingredients. Adjacent links are bundled to reduce the clutter. Note that the map shows only the statistically significant links, as identified by the algorithm of Ref. [41] for prevalence 10% . A drawing of the full network is too dense to be informative. We see, however, the full network in our subsequent measurements.

Fig. 2. Modeling the emergence of collaboration networks in creative activities. (A) Creation of a network with $n = 5$ agents. (B) Example of time series of collaboration network constructed from agents' all recruitment lists. (C) Example of time series of recruitment lists. (D) A large and connected network (circle) available to participate in new teams. Each agent in a team has a probability p of being chosen from the pool of recruitment lists. (E) A set of being chosen from the pool of recruitment lists. (F) For the second and subsequent agents selected from the recruitment pool (i) with probability p , the new agent is randomly selected from among the set of collaborations of a randomly selected incumbent already in the team. (ii) otherwise, he or she is selected at random among all incumbents in the network. (iii) Components in an network that incumbent is selected as the first agent in the new team (bottom box) or as an incumbent in the second agent in recruitment list (middle box). In this example, the second agent is a past collaborator of agent 4, specifically agent 3 (center-right box). Lastly, the third agent is selected from the pool of incumbents; this agent becomes a collaborator (rightmost box). In these boxes and in the following panels and figures, blue lines indicate recommender-incumbent collaborations, green lines indicate recommender-recruitment collaborations, yellow lines indicate new recruitment-recruitment collaborations, and red lines indicate repeat collaborations. (B) Time evolution of the network of collaborations according to the model for $p = 0.5$, $q = 0.5$, and $n = 5$.

Generating functionology [115]

- Idea: Given a sequence a_0, a_1, a_2, \dots , associate each element with a distinct function or other mathematical object.
- Well-chosen functions allow us to manipulate sequences and retrieve sequence elements.

Definition:

The **generating function** (g.f.) for a sequence $\{a_n\}$ is

$$F(x) = \sum_{n=0}^{\infty} a_n x^n.$$

- Roughly: transforms a vector in R^∞ into a function defined on R^1 .
- Related to Fourier, Laplace, Mellin, ...

Simple examples:

Rolling dice and flipping coins:

- $p_k^{(d)} = \Pr(\text{throwing a } k) = 1/6$ where $k = 1, 2, \dots, 6$.

$$F^{(d)}(x) = \sum_{k=1}^6 p_k^{(d)} x^k = \frac{1}{6}(x + x^2 + x^3 + x^4 + x^5 + x^6).$$

- $p_0^{(\text{coin})} = \Pr(\text{head}) = 1/2, p_1^{(\text{coin})} = \Pr(\text{tail}) = 1/2$.

$$F^{(\text{coin})}(x) = p_0^{(\text{coin})} x^0 + p_1^{(\text{coin})} x^1 = \frac{1}{2}(1 + x).$$

- A generating function for a probability distribution is called a **Probability Generating Function** (p.g.f.).
- We'll come back to these simple examples as we derive various delicious properties of generating functions.

Useful pieces for probability distributions:

- Normalization: $F(1) = 1$

- First moment: $\langle k \rangle = F'(1)$

- Higher moments: $\langle k^n \rangle = \left(x \frac{d}{dx} \right)^n F(x) \Big|_{x=1}$

- k th element of sequence (general):

$$P_k = \frac{1}{k!} \frac{d^k}{dx^k} F(x) \Big|_{x=0}$$

Random bipartite networks:

We'll follow this rather well cited paper:

"Random graphs with arbitrary degree distributions and their applications"
Newman, Strogatz, and Watts,
Phys. Rev. E, **64**, 026118, 2001. [80]

Example of a bipartite affiliation network and the induced networks:

- Center: A small story-trope bipartite graph. [28]
- Induced trope network and the induced story network are on the left and right.
- The dashed edge in the bipartite affiliation network indicates an edge added to the system, resulting in the dashed edges being added to the two induced networks.

Basic story:

- An example of two inter-affiliated types:
 - ☞ \mathbb{E} = stories,
 - ☞ \mathbb{V} = tropes.
- Stories contain tropes, tropes are in stories.
- Consider a story-trope system with $N_{\mathbb{E}}$ = # stories and $N_{\mathbb{V}}$ = # tropes.
- $m_{\mathbb{E},\mathbb{V}}$ = number of edges between \mathbb{E} and \mathbb{V} .
- Let's have some underlying distributions for numbers of affiliations: $P_k^{(\mathbb{E})}$ (a story has k tropes) and $P_k^{(\mathbb{V})}$ (a trope is in k stories).
- Average number of affiliations: $\langle k \rangle_{\mathbb{E}}$ and $\langle k \rangle_{\mathbb{V}}$.
 - ☞ $\langle k \rangle_{\mathbb{E}}$ = average number of tropes per story.
 - ☞ $\langle k \rangle_{\mathbb{V}}$ = average number of stories containing a given trope.
- Must have balance: $N_{\mathbb{E}} \cdot \langle k \rangle_{\mathbb{E}} = m_{\mathbb{E},\mathbb{V}} = N_{\mathbb{V}} \cdot \langle k \rangle_{\mathbb{V}}$.

Spreading through bipartite networks:

- View as bouncing back and forth between the two connected populations. [28]
- Actual spread may be within only one population (ideas between people) or through both (failures in physical and communication networks).
- The gain ratio for simple contagion on a bipartite random network = product of two gain ratios.

Usual helpers for understanding network's structure:

- Randomly select an edge connecting a \mathbb{E} to a \mathbb{V} .
- Probability the \mathbb{E} contains k other tropes:

$$R_k^{(\mathbb{E})} = \frac{(k+1)P_{k+1}^{(\mathbb{E})}}{\sum_{j=0}^{N_{\mathbb{E}}} (j+1)P_{j+1}^{(\mathbb{E})}} = \frac{(k+1)P_{k+1}^{(\mathbb{E})}}{\langle k \rangle_{\mathbb{E}}}$$
- Probability the \mathbb{V} is in k other stories:

$$R_k^{(\mathbb{V})} = \frac{(k+1)P_{k+1}^{(\mathbb{V})}}{\sum_{j=0}^{N_{\mathbb{V}}} (j+1)P_{j+1}^{(\mathbb{V})}} = \frac{(k+1)P_{k+1}^{(\mathbb{V})}}{\langle k \rangle_{\mathbb{V}}}$$

Networks of \mathbb{E} and \mathbb{V} within bipartite structure:

- $P_{ind,k}^{(\mathbb{E})}$ = probability a random \mathbb{E} is connected to k stories by sharing at least one \mathbb{V} .
- $P_{ind,k}^{(\mathbb{V})}$ = probability a random \mathbb{V} is connected to k tropes by co-occurring in at least one \mathbb{E} .
- $R_{ind,k}^{(\mathbb{V}-\mathbb{E})}$ = probability a random edge leads to a \mathbb{E} which is connected to k other stories by sharing at least one \mathbb{V} .
- $R_{ind,k}^{(\mathbb{E}-\mathbb{V})}$ = probability a random edge leads to a \mathbb{V} which is connected to k other tropes by co-occurring in at least one \mathbb{E} .
- Goal: find these distributions \square .
- Another goal: find the induced distribution of component sizes and a test for the presence or absence of a giant component.
- Unrelated goal: be 10% happier/weep less.

Unstoppable spreading: Is this thing connected?

- Always about the edges: when following a random edge toward a \mathbb{E} , what's the expected number of new edges leading to other stories via tropes?
- We want to determine $\langle k \rangle_{R,\mathbb{E},ind} = F'_{R,\mathbb{E},ind}(1)$ (and $F'_{R,\mathbb{E},ind}(1)$ for the trope side of things).
- We compute with joy:

$$\begin{aligned} \langle k \rangle_{R,\mathbb{E},ind} &= \left. \frac{d}{dx} F_{R,\mathbb{E},ind}(x) \right|_{x=1} = \left. \frac{d}{dx} F_{R,\mathbb{E}}(F_{R,\mathbb{V}}(x)) \right|_{x=1} \\ &= F'_{R,\mathbb{V}}(1) F'_{R,\mathbb{E}}(F_{R,\mathbb{V}}(1)) = F'_{R,\mathbb{V}}(1) F'_{R,\mathbb{E}}(1) = \frac{F''_{P,\mathbb{V}}(1) F''_{P,\mathbb{E}}(1)}{F'_{P,\mathbb{V}}(1) F'_{P,\mathbb{E}}(1)} \end{aligned}$$

- Note symmetry.
- \$happiness++;

- In terms of the underlying distributions:

$$\langle k \rangle_{R,\mathbb{E},ind} = \frac{\langle k(k-1) \rangle_{\mathbb{E}} \langle k(k-1) \rangle_{\mathbb{V}}}{\langle k \rangle_{\mathbb{E}} \langle k \rangle_{\mathbb{V}}}$$

- We have a giant component in both induced networks when

$$\langle k \rangle_{R,\mathbb{E},ind} \equiv \langle k \rangle_{R,\mathbb{V},ind} > 1$$

- See this as the product of two gain ratios. #excellent #physics

- We can mess with this condition to make it mathematically pleasant and pleasantly inscrutable:

$$\sum_{k=0}^{\infty} \sum_{k'=0}^{\infty} k k' (k k' - k - k') P_k^{(\mathbb{E})} P_{k'}^{(\mathbb{V})} = 0.$$

Betweenness for electrons:

- Unit resistors on each edge.
- For every pair of nodes s (source) and t (sink), set up **unit currents** in at s and out at t .
- Measure absolute current along each edge ℓ , $|I_{\ell, st}|$.

- Sum $|I_{\ell, st}|$ over all pairs of nodes to obtain **electronic betweenness** for edge ℓ . (Equivalent to **random walk betweenness**.)
- Contributing electronic betweenness for edge between nodes i and j :

$$B_{ij, st}^{elec} = a_{ij} |V_{i, st} - V_{j, st}|.$$

Electronic betweenness

- Define some arbitrary voltage reference.
- Kirchhoff's laws: current flowing out of node i must balance:

$$\sum_{j=1}^N \frac{1}{R_{ij}} (V_j - V_i) = \delta_{is} - \delta_{it}.$$

- Between connected nodes, $R_{ij} = 1 = a_{ij} = 1/a_{ij}$.
- Between unconnected nodes, $R_{ij} = \infty = 1/a_{ij}$.
- We can therefore write:

$$\sum_{j=1}^N a_{ij} (V_i - V_j) = \delta_{is} - \delta_{it}.$$

- Some gentle jiggery-pokery on the left hand side: $\sum_j a_{ij} (V_i - V_j) = V_i \sum_j a_{ij} - \sum_j a_{ij} V_j = V_i k_i - \sum_j a_{ij} V_j = \sum_j [k_i \delta_{ij} V_j - a_{ij} V_j] = [(\mathbf{K} - \mathbf{A})\vec{V}]_i$

Hierarchy by division

One class of structure-detection algorithms:

- Compute edge betweenness for whole network.
- Remove edge with highest betweenness.
- Recompute edge betweenness
- Repeat steps 2 and 3 until all edges are removed.
- Record when components appear as a function of # edges removed.
- Generate **dendrogram** revealing hierarchical structure.

Red line indicates appearance of four (4) components at a certain level.

Electronic betweenness

- Write right hand side as $[I^{ext}]_{i, st} = \delta_{is} - \delta_{it}$, where I_{st}^{ext} holds external source and sink currents.
- Matrixingly then:

$$(\mathbf{K} - \mathbf{A})\vec{V} = I_{st}^{ext}.$$

- $\mathbf{L} = \mathbf{K} - \mathbf{A}$ is a beast of some utility—known as the **Laplacian**.
- Solve for voltage vector \vec{V} by **LU decomposition** (Gaussian elimination).
- Do not compute an inverse!
- Note:** voltage offset is arbitrary so no unique solution.
- Presuming network has one component, null space of $\mathbf{K} - \mathbf{A}$ is one dimensional.
- In fact, $\mathcal{N}(\mathbf{K} - \mathbf{A}) = \{c\vec{1}, c \in R\}$ since $(\mathbf{K} - \mathbf{A})\vec{1} = \vec{0}$.

Alternate betweenness measures:

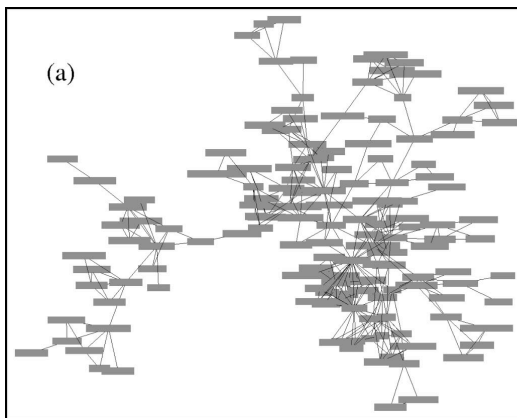

Random walk betweenness:

- Asking too much: Need full knowledge of network to travel along shortest paths.
- One of many alternatives: consider all **random walks** between pairs of nodes i and j .
- Walks starts at node i , traverses the network randomly, ending as soon as it reaches j .
- Record the number of times an edge is followed by a walk.
- Consider all pairs of nodes.
- Random walk betweenness of an edge = absolute difference in probability a random walk travels one way versus the other along the edge.
- Equivalent to electronic betweenness (see also diffusion).

Warnings:

- Networks aren't everything.
- Famous models of networks aren't everything in networks.
- Mathematical tractability ≠ meaningfulness or viable existence in reality
- Even when networks are core to a system, the best level of analysis may involve some scale of grouping/averaging.
- Groups, groups, groups.
- And pyramids (~ hierarchies)

“Link communities reveal multiscale complexity in networks”

Nutshell:

Overview Key Points:

- The field of complex networks came into existence in the late 1990s.
- Explosion of papers and interest since 1998/99.
- Hardened up much thinking about complex systems.
- Specific focus on networks that are **large-scale, sparse, natural or people-made, evolving and dynamic, and (crucially) measurable.**
- Three main (blurred) categories:
 - Physical (e.g., river networks),
 - Interactional (e.g., social networks),
 - Abstract (e.g., thesauri).
- To solve network problems: “Follow the edges.”

More Allegations:

- The map is not the territory.
- Sometimes the map is not the territory because the territory does not exist.
- “But it might one day!” yelled Captain Survivor Bias IV while holding up two pineapples to gauge the distance between waves.
- And the mapper is never the map.
- (Scientific truths shouldn't be named after individuals.)

The absolute basics:

Modern basic science in three steps:

1. Find interesting/meaningful/important phenomena, optionally involving spectacular amounts of data.
2. Describe what you see.
3. Explain it.

If you succeed at 1–3:

4. Create.
5. Share.

Always:

6. Be good people.
