Covered in these episode(s) and clip

Episode 1: The OG rich-get-richer model (1:52:03)

Clip 1: Intro to Simon vs Mandebrot and the mechanism of rich-get-richerness (6:35)

Clip 2: Observations of Zipferv. 1910 on (12:13)

Clip 3: Herbert Simon #awesomeness (2:18)

Clip 4: Toy model of rich-get-richer (14:51)

Clip 5: Observations about our toy model (7:10)

Clip 6: Krugman's math woes (1:34)

Clip 7: We work through an analysis (14:37)

Clip 8: What we find: Micro-to-macro story and surprising agreement with reality (8:30)

Clip 9: An appraisal of catchphrases (3:53)

Clip 10: Simon's model recap (3:47)

Exciting details regarding these slides:

- Three servings (all in pdf):
 - 1. Fresh: For in-class Deliveration.
 - 2. On toast: Flattened for page-turning joy.
 - 3. Freeze-dried: Pack-and-go, 3x3 slides per page.
- Presentation versions are hyperly navigable:

 → • = back + search + forward.
- Web links look like this ☑.
- References in slides link to full citation at end. [4]
- Citations contain links to pdfs for papers (if available).
- Some books will be linked to on Amazon.
- Brought to you by a frightening melange of XAMEXC, Beamer , perl , PerlTeXC, fevered command-line madness , and an almost fanatical devotion to the indomitable emacs . #totallynormal

The Science of Complex Systems Manifesto:

- 1. Systems are ubiquitous and systems matter.
- 2. Consequently, much of science is about understanding how pieces dynamically fit together.
- 3. 1700 to 2000 = Golden Age of Reductionism: Atoms!, sub-atomic particles, DNA, genes, people, ...
- 4. Understanding and creating systems (including new 'atoms') is the greater part of science and engineering.
- 5. Universality : systems with quantitatively different micro details exhibit qualitatively similar macro behavior.
- 6. Computing advances make the Science of Complex Systems possible:
 - 6.1 We can measure and record enormous amounts of data, research areas continue to transition from data scarce to data rich.
 - 6.2 We can simulate, model, and create complex systems in extraordinary detail.

net•work | 'net,wərk |

noun

1 an arrangement of intersecting horizontal and vertical lines.

- a complex system of roads, railroads, or other transportation routes:
 a network of railroads.
- 2 a group or system of interconnected people or things: a trade network.
 - a group of people who exchange information, contacts, and experience for professional or social purposes : a support network.
 - a group of broadcasting stations that connect for the simultaneous broadcast of a program: the introduction of a second TV network | [as adj.] network television.
 - a number of interconnected computers, machines, or operations: specialized computers that manage multiple outside connections to a network | a local cellular phone network.
 - a system of connected electrical conductors.

verb [trans.]

connect as or operate with a network: the stock exchanges have proven to be resourceful in networking these deals.

- link (machines, esp. computers) to operate interactively : [as adj.] (**networked**) networked workstations.
- [intrans.] [often as n.] (**networking**) interact with other people to exchange information and develop contacts, esp. to further one's career: the skills of networking, bargaining, and negotiation.

Ancestry:

Net and Work are venerable old words:

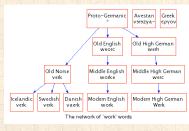

'Net' first used to mean spider web (King Ælfréd, 888).

'Work' appear to have long meant purposeful action.

'Network' = something built based on the idea of natural, flexible lattice or web.

c.f., ironwork, stonework, fretwork.

Key Observation:

- Many complex systems can be viewed as complex networks of physical or abstract interactions.
- Opens door to mathematical and numerical analysis.
- Dominant approach of the first decade was of a theoretical-physics/stat-mechish flavor.
- Mindboggling amount of work published on complex networks since 1998 ...
- ... largely due to your typical theoretical physicist:
 - Piranha physicus
 - Hunt in packs.
 - Feast on new and interesting ideas (see chaos, cellular automata, ...)

More observations

But surely networks aren't new ...

Graph theory was well established ...

Study of social networks started in the 1930's ...

So why all this 'new' research on networks?

Answer: Oodles of Easily Accessible Data.

We can now inform (alas) our theories with a much more measurable reality.*

Graph theory missed "becoming": Stories = Characters + Time

A worthy goal: establish mechanistic explanations.

*If this is upsetting, maybe string theory is for you ...

Major Models Generalized Affiliation Thresholds

Generating

Structure Detection

Big Nutshell

Super Basic definitions

Node degree = Number of links per node

 \aleph Notation: Node *i*'s degree = k_i .

 $\& k_i = 0,1,2,...$

Notation: the average degree of a network = $\langle k \rangle$ (and sometimes z)

& Connection between number of edges m and average degree:

 $\langle k \rangle = \frac{2m}{N}.$

 \bowtie Defn: \mathcal{N}_i = the set of i's k_i neighbors

Super Basic definitions

Adjacency matrix:

We can represent a network by a matrix A with link weight a_{ij} for nodes i and j in entry (i,j).

🖀 e.g.,

$$A = \left[\begin{array}{ccccc} 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \end{array} \right]$$

- For numerical work, we always use sparse matrices.
- For many real networks, A is a function of time.

A notable feature of large-scale networks:

Graphical renderings are often just a big mess.

← Typical hairball

- number of nodes N = 500
- number of edges m = 1000
- average degree $\langle k \rangle$ = 4

And even when renderings somehow look good: "That is a very graphic analogy which aids understanding wonderfully while being, strictly speaking, wrong in every possible way" said Ponder [Stibbons] — Making Money, T. Pratchett.

We need to extract digestible, meaningful aspects.

1. degree distribution P_k

 $\begin{subarray}{ll} \& P_k \end{subarray}$ is the probability that a randomly selected node has degree k.

& k = node degree = number of connections.

ex 1: Erdős-Rényi random networks have Poisson degree distributions:

$$P_k = e^{-\langle k \rangle} \frac{\langle k \rangle^k}{k!}$$

 \Leftrightarrow ex 2: "Scale-free" networks: $P_k \propto k^{-\gamma} \Rightarrow$ 'hubs'.

link cost controls skew.

hubs may facilitate or impede contagion.

Major Models Generalized Affiliation Thresholds

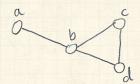

Generating

Structure Detection

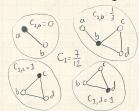

Big Nutshell

Example network:

Calculation of C_1 :

pairs of neighbors who are connected.

Fraction of pairs of neighbors who are connected is

$$\frac{\sum_{j_1j_2\in\mathcal{N}_i}a_{j_1j_2}}{k_i(k_i-1)/2}$$

where k_i is node i's degree, and \mathcal{N}_i is the set of i's neighbors.

Averaging over all nodes, we have:

$$C_1 = \frac{1}{n} \sum_{i=1}^{n} \frac{\sum_{j_1 j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i (k_i - 1)/2} = \left\langle \frac{\sum_{j_1 j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i (k_i - 1)/2} \right\rangle_i$$

Triples and triangles

Example network:

Triangles:

Triples:

- $lap{Nodes } i_1, i_2, ext{ and } i_3 ext{ form a}$ $lap{triple around } i_1 ext{ if } i_1 ext{ is}$ $lap{connected to } i_2 ext{ and } i_3.$
- Nodes i_1 , i_2 , and i_3 form a triangle if each pair of nodes is connected
- $\text{The definition } C_2 = \frac{3 \times \text{\#triangles}}{\text{\#triples}}$ measures the fraction of closed triples
- The '3' appears because for each triangle, we have 3 closed triples.
- Social Network Analysis (SNA): fraction of transitive triples.

Clustering:

Sneaky counting for undirected, unweighted networks:

 $\begin{cases} \& \end{cases}$ If the path i-j- ℓ exists then $a_{ij}a_{j\ell}=1$.

 \clubsuit We want $i \neq \ell$ for good triples.

In general, a path of n edges between nodes i_1 and i_n travelling through nodes i_2 , i_3 , ... i_{n-1} exists $\Leftrightarrow a_{i_1i_2}a_{i_2i_3}a_{i_2i_4}\cdots a_{i_{n-1}i_{n-1}}a_{i_{n-1}i_n}=1$.

$$\# \mathsf{triples} = \frac{1}{2} \left(\sum_{i=1}^{N} \sum_{\ell=1}^{N} \left[A^2 \right]_{i\ell} - \mathsf{Tr} A^2 \right)$$

$$\# triangles = \frac{1}{6} Tr A^3$$

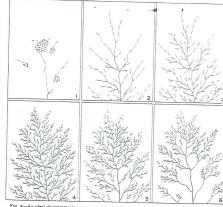

Fig. 8—An ideal diagrammatic summary of the development of a drainage system given for purposes of comparison only. The first four parts show extension, thus: 1. initiation; 2. elongation; 3. elaboration; and 4. maximum extension. Parts 3 and 5 represent steeps during integration.

The sequential stages recognized in the evolution of a drainage system are "extension" and "integration"; the first, a stage of increasing complexity; the second, of simplification.

'Laws'

A Hack's law (1957) [50]:

$$\ell \propto a^h$$

reportedly 0.5 < h < 0.7

Scaling of main stream length with basin size:

$$\ell \propto L_{\parallel}^d$$

reportedly 1.0 < d < 1.1

Basin allometry:

$$L_{\parallel} \propto a^{h/d} \equiv a^{1/D}$$

 $D < 2 \rightarrow$ basins elongate.

There are a few more 'laws': [31]

Horton's laws

Self-similarity of river networks

First quantified by Horton (1945)^[53], expanded by Schumm (1956) [88]

Three laws:

Horton's law of stream numbers:

$$n_{\omega}/n_{\omega+1} = R_n > 1$$

Horton's law of stream lengths:

$$\bar{\ell}_{\omega+1}/\bar{\ell}_{\omega} = R_{\ell} > 1$$

Horton's law of basin areas:

$$\bar{a}_{\omega+1}/\bar{a}_{\omega} = R_a > 1$$

Deriving the optimal source distribution:

- Basic idea: Minimize the average distance from a random individual to the nearest facility. [40]
- Assume given a fixed population density ρ_{pop} defined on a spatial region Ω .
- Formally, we want to find the locations of n sources $\{\vec{x}_1,\dots,\vec{x}_n\}$ that minimizes the cost function

$$F(\{\vec{x}_1,\dots,\vec{x}_n\}) = \int_{\Omega} \frac{\rho_{\mathsf{pop}}(\vec{x}) \, \mathsf{min}_i ||\vec{x} - \vec{x}_i|| \mathsf{d}\vec{x} \,.$$

- Also known as the p-median problem, and connected to cluster analysis.
- Not easy ...in fact this one is an NP-hard problem. [40]
- Approximate solution originally due to Gusein-Zade [49].

Global redistribution networks

One more thing:

- How do we supply these facilities?
- How do we best redistribute mail? People?
- A How do we get beer to the pubs?
- Gastner and Newman model: cost is a function of basic maintenance and travel time:

$$C_{\mathsf{maint}} + \gamma C_{\mathsf{travel}}.$$

Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance ℓ_{ij} and number of legs to journey:

$$(1-\delta)\ell_{ij} + \delta(\#\mathsf{hops}).$$

& When $\delta = 1$, only number of hops matters.

Public versus private facilities

Beyond minimizing distances:

- "Scaling laws between population and facility densities" by Um et al., Proc. Natl. Acad. Sci., 2009. [104]
- When the connection between facility and population density

$$ho_{
m fac} \propto
ho_{
m pop}^{lpha}$$

does not universally hold with $\alpha = 2/3$.

- Two idealized limiting classes:
 - 1. For-profit, commercial facilities: $\alpha = 1$;
 - 2. Pro-social, public facilities: $\alpha = 2/3$.
 - Um et al. investigate facility locations in the United States and South Korea.

Big Nutshell

Limiting form of P(k; p, N):

- Our degree distribution: $P(k; p, N) = \binom{N-1}{k} p^k (1-p)^{N-1-k}.$
- We must end up with the normal distribution right?
- \implies If p is fixed, then we would end up with a Gaussian with average degree $\langle k \rangle \simeq pN \to \infty$.
- \clubsuit But we want to keep $\langle k \rangle$ fixed ...
- So examine limit of P(k;p,N) when $p\to 0$ and $N\to \infty$ with $\langle k\rangle=p(N-1)$ = constant.

$$P(k;p,N) \simeq \frac{\langle k \rangle^k}{k!} \left(1 - \frac{\langle k \rangle}{N-1}\right)^{N-1-k} \to \frac{\langle k \rangle^k}{k!} e^{-\langle k \rangle}$$

 $\mbox{\&}$ This is a Poisson distribution $\mbox{\&}$ with mean $\langle k \rangle$.

The edge-degree distribution:

- $\ref{eq:constraint}$ The degree distribution P_k is fundamental for our description of many complex networks
- $\ensuremath{\mathfrak{S}}$ Again: P_k is the degree of randomly chosen node.
- A second very important distribution arises from choosing randomly on edges rather than on nodes.
- Define Q_k to be the probability the node at a random end of a randomly chosen edge has degree k.
- Now choosing nodes based on their degree (i.e., size):

$$Q_k \propto k P_k$$

Normalized form:

$$Q_k = \frac{kP_k}{\sum_{k'=0}^{\infty} k' P_{k'}} = \frac{kP_k}{\langle k \rangle}.$$

Big deal: Rich-get-richer mechanism is built into this selection process.

The edge-degree distribution:

For networks, Q_k is also the probability that a friend (neighbor) of a random node has k friends.

 \triangle Useful variant on Q_{ν} :

 R_{k} = probability that a friend of a random node has k other friends.

$$R_k = \frac{(k+1)P_{k+1}}{\sum_{k'=0}(k'+1)P_{k'+1}} = \frac{(k+1)P_{k+1}}{\langle k \rangle}$$

Equivalent to friend having degree k + 1.

Natural question: what's the expected number of other friends that one friend has?

Probability of randomly selecting a node of degree k by choosing from nodes:

$$P_1 = 3/7, P_2 = 2/7, P_3 = 1/7, P_6 = 1/7.$$

Probability of landing on a node of degree k after randomly selecting an edge and then randomly choosing one direction to travel:

$$Q_1=3/16,\,Q_2=4/16,\ Q_3=3/16,\,Q_6=6/16.$$

Probability of finding # outgoing edges = k after randomly selecting an edge and then randomly choosing one direction to travel:

$$\begin{split} R_0 &= 3/16 \; R_1 = 4/16, \\ R_2 &= 3/16, \, R_5 = 6/16. \end{split}$$

Generalized Affiliation
Networks

Thresholds

Generating Functions

Structure Detection

Big Nutshell

Two reasons why this matters

Reason #1:

Average # friends of friends per node is

$$\langle k_2 \rangle = \langle k \rangle \times \langle k \rangle_R = \langle k \rangle \frac{1}{\langle k \rangle} \left(\langle k^2 \rangle - \langle k \rangle \right) = \langle k^2 \rangle - \langle k \rangle.$$

- \Leftrightarrow Key: Average depends on the 1st and 2nd moments of P_k and not just the 1st moment.
- Three peculiarities:
 - 1. We might guess $\langle k_2 \rangle = \langle k \rangle (\langle k \rangle 1)$ but it's actually $\langle k(k-1) \rangle$.
 - 2. If P_k has a large second moment, then $\langle k_2 \rangle$ will be big. (e.g., in the case of a power-law distribution)
 - 3. Your friends really are different from you ... [37, 76]
 - 4. See also: class size paradoxes (nod to: Gelman)

¹Some press here [MIT Tech Review].

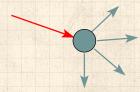

Spreading on Random Networks

For random networks, we know local structure is pure branching.

Successful spreading is a contingent on single edges infecting nodes.

Success Failure:

Focus on binary case with edges and nodes either infected or not.

First big question: for a given network and contagion process, can global spreading from a single seed occur? The PoCSverse Complex Networks 145 of 321

Global spreading condition

& We need to find: [30]

R = the average # of infected edges that one random infected edge brings about.

& Call **R** the gain ratio.

Define B_{k1} as the probability that a node of degree k is infected by a single infected edge.

$$\mathbf{R} = \sum_{k=0}^{\infty} \frac{\frac{kP_k}{\langle k \rangle}}{\text{prob. of } \atop \text{connecting to } \atop \text{a degree } k \text{ node}}$$

$$\underbrace{(k-1)}_{\text{\# outgoing infected edges}} \bullet \underbrace{B_{k1}}_{\text{Prob. of infection}}$$

$$+\sum_{k=0}^{\infty}\frac{\widehat{kP_k}}{\langle k\rangle} \bullet \underbrace{0}_{\begin{subarray}{c} \text{# outgoing infected} \\ \text{edges} \end{subarray}} \bullet \underbrace{(1-B_{k1})}_{\begin{subarray}{c} \text{Prob. of } \\ \text{no infection} \end{subarray}}$$

Random directed networks:

So far, we've largely studied networks with undirected, unweighted edges.

Nodes have k_i and k_o incoming and outgoing edges, otherwise random.

 $lap{Network}$ Network defined by joint in- and out-degree distribution: P_{k_1,k_0}

$$\ \ \,$$
 Normalization: $\sum_{k_{\rm i}=0}^{\infty} \sum_{k_{\rm o}=0}^{\infty} P_{k_{\rm i},k_{\rm o}} = 1$

Marginal in-degree and out-degree distributions:

$$P_{k_{\rm i}} = \sum_{k_{\rm o}=0}^{\infty} P_{k_{\rm i},k_{\rm o}} \text{ and } P_{k_{\rm o}} = \sum_{k_{\rm i}=0}^{\infty} P_{k_{\rm i},k_{\rm o}}$$

Required balance:

$$\langle k_{\rm i}\rangle = \sum_{k_{\rm i}=0}^{\infty} \sum_{k_{\rm o}=0}^{\infty} k_{\rm i} P_{k_{\rm i},k_{\rm o}} = \sum_{k_{\rm i}=0}^{\infty} \sum_{k_{\rm o}=0}^{\infty} k_{\rm o} P_{k_{\rm i},k_{\rm o}} = \langle k_{\rm o}\rangle$$

References

When moving through a family of increasingly connected directed random networks, GWCC usually appears before GIN, GOUT, and GSCC which tend to appear together. [80, 15]

Observation:

Directed and undirected random networks are separate families ...

🚓 ...and analyses are also disjoint.

Need to examine a larger family of random networks with mixed directed and undirected edges.

Consider nodes with three types of edges:

- 1. k_u undirected edges,
- 2. k_i incoming directed edges,
- 3. k_0 outgoing directed edges.

Define a node by generalized degree:

$$\vec{k} = [\ k_{\mathsf{u}} \ k_{\mathsf{i}} \ k_{\mathsf{o}} \]^{\mathsf{T}}.$$

Correlations:

🙈 Now add correlations (two point or Markovian) 🛭:

- 1. $P^{(u)}(\vec{k} \mid \vec{k}')$ = probability that an undirected edge leaving a degree \vec{k}' nodes arrives at a degree \vec{k} node.
- 2. $P^{(i)}(\vec{k} | \vec{k}')$ = probability that an edge leaving a degree \vec{k}' nodes arrives at a degree \vec{k} node is an in-directed edge relative to the destination node.
- 3. $P^{(0)}(\vec{k} | \vec{k}')$ = probability that an edge leaving a degree \vec{k}' nodes arrives at a degree \vec{k} node is an out-directed edge relative to the destination node.

Now require more refined (detailed) balance.

Conditional probabilities cannot be arbitrary.

- 1. $P^{(u)}(\vec{k} | \vec{k}')$ must be related to $P^{(u)}(\vec{k}' | \vec{k})$.
- 2. $P^{(0)}(\vec{k} | \vec{k}')$ and $P^{(i)}(\vec{k} | \vec{k}')$ must be connected.

Correlations—Undirected edge balance:

- Randomly choose an edge, and randomly choose one end.
- Say we find a degree \vec{k} node at this end, and a degree \vec{k}' node at the other end.
- Define probability this happens as $P^{(u)}(\vec{k}, \vec{k}')$.
- Observe we must have $P^{(u)}(\vec{k}, \vec{k}') = P^{(u)}(\vec{k}', \vec{k})$.

Conditional probability connection:

$$P^{(\mathsf{u})}(\vec{k}, \vec{k}') = P^{(\mathsf{u})}(\vec{k} \,|\, \vec{k}') \frac{k'_\mathsf{u} P(\vec{k}')}{\langle k'_\mathsf{u} \rangle}$$

$$P^{(\mathrm{u})}(\vec{k}',\vec{k}) \ = \ P^{(\mathrm{u})}(\vec{k}'\,|\,\vec{k}) \frac{k_\mathrm{u} P(\vec{k})}{\langle k_\mathrm{u} \rangle}. \label{eq:purple}$$

Structure

Big Nutshell

Correlations—Directed edge balance:

The quantities

$$\frac{k_{\rm o}P(\vec{k})}{\langle k_{\rm o}\rangle}$$
 and $\frac{k_{\rm i}P(\vec{k})}{\langle k_{\rm i}\rangle}$

give the probabilities that in starting at a random end of a randomly selected edge, we begin at a degree \vec{k} node and then find ourselves travelling:

- 1. along an outgoing edge, or
- 2. against the direction of an incoming edge.

We therefore have

$$P^{(\mathrm{dir})}(\vec{k},\vec{k}') = P^{(\mathrm{i})}(\vec{k}\,|\,\vec{k}') \frac{k_{\mathrm{o}}'P(\vec{k}')}{\langle k_{\mathrm{o}}' \rangle} = P^{(\mathrm{o})}(\vec{k}'\,|\,\vec{k}) \frac{k_{\mathrm{i}}P(\vec{k})}{\langle k_{\mathrm{i}} \rangle}. \label{eq:policy}$$

Note that $P^{(\text{dir})}(\vec{k}, \vec{k}')$ and $P^{(\text{dir})}(\vec{k}', \vec{k})$ are in general not related if $\vec{k} \neq \vec{k}'$.

Full generalization:

$$f_{\vec{\alpha}}(d+1) = \sum_{\vec{\alpha}'} R_{\vec{\alpha}\,\vec{\alpha}'} f_{\vec{\alpha}'}(d)$$

 $R_{\vec{\alpha}\vec{\alpha}'}$ is the gain ratio matrix and has the form:

$$R_{\vec{\alpha}\vec{\alpha}'} = P_{\vec{\alpha}\vec{\alpha}'} \bullet k_{\vec{\alpha}\vec{\alpha}'} \bullet B_{\vec{\alpha}\vec{\alpha}'}.$$

- $P_{\vec{\alpha}\vec{\alpha}'}$ = conditional probability that a type λ' edge emanating from a type ν' node leads to a type ν node.
- $\&k_{\vec{\alpha}\vec{\alpha}'}$ = potential number of newly infected edges of type λ emanating from nodes of type ν .
- & $B_{\vec{\alpha}\vec{\alpha}'}$ = probability that a type ν node is eventually infected by a single infected type λ' link arriving from a neighboring node of type ν' .
- Generalized contagion condition:

$$\max |\mu|: \mu \in \sigma\left(\mathbf{R}\right) > 1$$

Some claims for social networks:

Social networks yes, but groups, groups, groups

Sufficiently large social groups are:

- 1. Fandoms.
- 2. Pyramid Schemes,
- 3. Or both.

Homo narrativus: Storytellers, believers, spreaders.

Stories ~ Characters + Time.

Characters are shortcuts to stories.

Essential Extract of a Growth Model:

Random Competitive Replication (RCR):

- 1. Start with 1 elephant (or element) of a particular flavor at t=1
- 2. At time t = 2, 3, 4, ..., add a new elephant in one of two ways:
 - With probability ρ , create a new elephant with a new flavor
 - = Mutation/Innovation
 - With probability $1-\rho$, randomly choose from all existing elephants, and make a copy.
 - = Replication/Imitation
 - Elephants of the same flavor form a group

Social contagion models

Thresholds

- Basic idea: individuals adopt a behavior when a certain fraction of others have adopted
- 'Others' may be everyone in a population, an individual's close friends, any reference group.
- Response can be probabilistic or deterministic.
- Individual thresholds can vary
- Assumption: order of others' adoption does not matter... (unrealistic).
- Assumption: level of influence per person is uniform (unrealistic).

Social Contagion

Some possible origins of thresholds:

- Inherent, evolution-devised inclination to coordinate, to conform, to imitate. [9]
- Lack of information: impute the worth of a good or behavior based on degree of adoption (social proof)
- Economics: Network effects or network externalities
 - Externalities = Effects on others not directly involved in a transaction
 - Examples: telephones, fax machine, TikTok, operating systems
 - An individual's utility increases with the adoption level among peers and the population in general

Threshold models—Nutshell

Implications for collective action theory:

- 1. Collective uniformity ⇒ individual uniformity
- 2. Small individual changes ⇒ large global changes
- 3. The stories/dynamics of complex systems are conceptually inaccessible for individual-centric narratives.
- 4. System stories live in left null space of our stories—we can't even see them.
- But we happily impose simplistic, individual-centric stories—we can't help ourselves .

Back to following a link:

- \ref{A} A randomly chosen link, traversed in a random direction, leads to a degree k node with probability $\propto kP_k$.
- \aleph Follows from there being k ways to connect to a node with degree k.
- Normalization:

$$\sum_{k=0}^{\infty} k P_k = \langle k \rangle$$

🚓 So

 $P(\text{linked node has degree }k) = \frac{kP_k}{\langle k \rangle}$

Social contagion

"Without followers, evil cannot spread." –Leonard Nimoy

Summary

- 'Influential vulnerables' are key to spread.
- Early adopters are mostly vulnerables.
- Vulnerable nodes important but not necessary.
- Groups may greatly facilitate spread.
- Seems that cascade condition is a global one.
- Most extreme/unexpected cascades occur in highly connected networks
- 'Influentials' are posterior constructs.
- Many potential influentials exist.

Social contagion

Implications

- Focus on the influential vulnerables.
- Create entities that can be transmitted successfully through many individuals rather than broadcast from one 'influential.'
- Only simple ideas can spread by word-of-mouth. (Idea of opinion leaders spreads well...)
- Want enough individuals who will adopt and display.
- Displaying can be passive = free (yo-yo's, fashion), or active = harder to achieve (political messages; even so: buttons and hats).
- Entities can be novel or designed to combine with others, e.g. block another one.

Networks and creativity:

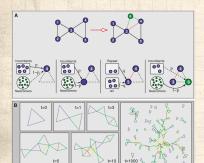

Fig. 2. Modeling the emergence of collaboration networks in creative enterprises. (A) Creation of a team with m = 3 agents. Consider, at time zero, a collaboration network comprising five agents, all incumbents (blue circles). Along with the incumbents, there is a large pool of newcomers (green circles) available to participate in new teams. Each agent in a team has a probability p of being drawn from the pool of incumbents and a probability 1 - p of being drawn from the pool of newcomers. For the second and subsequent agents selected from the incumbents' pool: (i) with probability q, the new agent is randomly selected from among the set of collaborators of a randomly selected incumbent already in the team: (iii) otherwise he or she is selected at random among all incumbents in the network. For concreteness, let us assume that incumbent 4 is selected as the first agent in the new team (leftmost box). Let us also assume that the second agent is an incumbent, too (center-left box). In this example, the second agent is a past collaborator of agent 4, specifically agent 3 (center-right box). Lastly, the third agent is selected from the pool of newcomers: this agent becomes incumbent 6 (rightmost box). In these boxes and in the following panels and figures, blue lines indicate newcomernewcomer collaborations, green lines indicate newcomer-incumbent collaborations, vellow lines indicate new incumbent-incumbent collaborations, and red lines indicate repeat collaborations. (B) Time evolution of the network of collaborations according to the model for p=0.5, q=0.5, and m=3.

Generatingfunctionology [115]

ldea: Given a sequence a_0, a_1, a_2, \dots , associate each element with a distinct function or other mathematical object.

Well-chosen functions allow us to manipulate sequences and retrieve sequence elements.

Definition:

 $lap{3}$ The generating function (g.f.) for a sequence $\{a_n\}$ is

$$F(x) = \sum_{n=0}^{\infty} a_n x^n.$$

Roughly: transforms a vector in R^{∞} into a function defined on R^1 .

🙈 Related to Fourier, Laplace, Mellin, ...

Basic story:

♀ = tropes ☑.

Stories contain tropes, tropes are in stories.

 $\ \ \,$ Consider a story-trope system with $N_{\ \ \ \ }$ = # stories and $N_{\ \ \ }$ = # tropes.

 $\gg m_{\boxminus, \lozenge}$ = number of edges between \boxminus and \lozenge .

Let's have some underlying distributions for numbers of affiliations: $P_k^{(\boxminus)}$ (a story has k tropes) and $P_k^{(\lozenge)}$ (a trope is in k stories).

 $\ensuremath{\&}$ Average number of affiliations: $\langle k \rangle_{\blacksquare}$ and $\langle k \rangle_{\ensuremath{\mathfrak{Q}}}$.

 $\langle k \rangle_{f ar B} =$ average number of tropes per story.

 $\langle k \rangle_{\mathbb{Q}}$ = average number of stories containing a given trope.

 $\red {\Bbb S}$ Must have balance: $N_{\blacksquare}\cdot \langle k \rangle_{\blacksquare}=m_{\blacksquare, \lozenge}=N_{\lozenge}\cdot \langle k \rangle_{\lozenge}.$

Generating Functions

Structure Detection

Big Nutshell

Unstoppable spreading: Is this thing connected?

- Always about the edges: when following a random edge toward a 🖽, what's the expected number of new edges leading to other stories via tropes?
- We compute with joy:

$$\begin{split} \langle k \rangle_{R,\boxminus,\mathrm{ind}} &= \left. \frac{\mathrm{d}}{\mathrm{d}x} F_{R^{(\!\mathbb{Q}-\!\!\!\square)}_{\mathrm{ind},k}}(x) \right|_{x=1} = \left. \frac{\mathrm{d}}{\mathrm{d}x} F_{R^{(\!\mathbb{Q}\!)}}\left(F_{R^{(\!\mathbb{Q}\!)}}(x)\right) \right|_{x=1} \\ &= F'_{R^{(\!\mathbb{Q}\!)}}(1) F'_{R^{(\!\mathbb{H}\!)}}\left(F_{R^{(\!\mathbb{Q}\!)}}(1)\right) = F'_{R^{(\!\mathbb{Q}\!)}}(1) F'_{R^{(\!\mathbb{H}\!)}}(1) = \frac{F''_{P^{(\!\mathbb{Q}\!)}}(1)}{F'_{P^{(\!\mathbb{H}\!)}}(1)} \frac{F''_{P^{(\!\mathbb{H}\!)}}(1)}{F'_{P^{(\!\mathbb{H}\!)}}(1)} \end{split}$$

- Note symmetry.
- \$happiness++;

In terms of the underlying distributions:

$$\langle k \rangle_{R, \boxminus, \mathrm{ind}} = \frac{\langle k(k-1) \rangle_{\boxminus}}{\langle k \rangle_{\boxminus}} \frac{\langle k(k-1) \rangle_{\lozenge}}{\langle k \rangle_{\lozenge}}$$

We have a giant component in both induced networks when

$$\langle k \rangle_{R,\blacksquare,\mathrm{ind}} \equiv \langle k \rangle_{R,\mathrm{V,ind}} > 1$$

- See this as the product of two gain ratios. #excellent #physics
- We can mess with this condition to make it mathematically pleasant and pleasantly inscrutable:

$$\sum_{k=0}^{\infty}\sum_{k'=0}^{\infty}kk'(kk'-k-k')P_k^{(\blacksquare)}P_{k'}^{(\lozenge)}=0.$$

Betweenness for electrons:

Unit resistors on each edge.

For every pair of nodes s (source) and t (sink), set up unit currents in at s and out at t.

Measure absolute current along each edge ℓ , $|I_{\ell,st}|$.

Sum $|I_{\ell,st}|$ over all pairs of nodes to obtain electronic betweenness for edge ℓ .

(Equivalent to random walk betweenness.)

Contributing electronic betweenness for edge between nodes i and j:

$$B_{ij,st}^{\text{elec}} = a_{ij}|V_{i,st} - V_{j,st}|.$$

Electronic betweenness

- Define some arbitrary voltage reference.
- Kirchhoff's laws: current flowing out of node i must balance:

$$\sum_{j=1}^N \frac{1}{R_{ij}}(V_j-V_i) = \delta_{is} - \delta_{it}.$$

- $\mathfrak{R}_{i,j} = 1 = a_{i,j} = 1/a_{i,j}$. Between connected nodes, $R_{i,j} = 1 = a_{i,j} = 1/a_{i,j}$.
- \Re Between unconnected nodes, $R_{ij} = \infty = 1/a_{ij}$.
- We can therefore write:

$$\sum_{j=1}^N a_{ij}(V_i-V_j) = \delta_{is} - \delta_{it}.$$

Some gentle jiggery-pokery on the left hand side:

$$\begin{array}{l} \sum_{j} a_{ij}(V_i - V_j) = \underbrace{V_i \sum_{j} a_{ij}} - \sum_{j} a_{ij} V_j \\ = V_i \underbrace{k_i} - \sum_{j} a_{ij} V_j = \sum_{j} \left[\underbrace{k_i \delta_{ij} V_j} - a_{ij} V_j \right] \\ = \left[(\mathbf{K} - \mathbf{A}) \vec{V} \right]_i \end{array}$$

Electronic betweenness

- \mathcal{R} Write right hand side as $[I^{\text{ext}}]_{i,st} = \delta_{is} \delta_{it}$, where I_{st}^{ext} holds external source and sink currents.
- Matrixingly then:

$$(\mathbf{K}-\mathbf{A})\vec{V}=I_{st}^{\mathrm{ext}}.$$

- $\mathbf{A} = \mathbf{K} \mathbf{A}$ is a beast of some utility—known as the Laplacian.
- \clubsuit Solve for voltage vector \vec{V} by **LU** decomposition (Gaussian elimination).
- Do not compute an inverse!
- Note: voltage offset is arbitrary so no unique solution.
- Presuming network has one component, null space of $\mathbf{K} - \mathbf{A}$ is one dimensional.
- In fact, $\mathcal{N}(\mathbf{K} \mathbf{A}) = \{c\vec{1}, c \in R\}$ since $(\mathbf{K} \mathbf{A})\vec{1} = \vec{0}$.

Alternate betweenness measures:

Random walk betweenness:

- Asking too much: Need full knowledge of network to travel along shortest paths.
- One of many alternatives: consider all random walks between pairs of nodes i and j.
- Walks starts at node i, traverses the network randomly, ending as soon as it reaches j.
- Record the number of times an edge is followed by a walk.
- Consider all pairs of nodes.
- Random walk betweenness of an edge = absolute difference in probability a random walk travels one way versus the other along the edge.
- Equivalent to electronic betweenness (see also diffusion).

Big Nutshell

Nutshell:

Overview Key Points:

- The field of complex networks came into existence in the late 1990s.
- Explosion of papers and interest since 1998/99.
- Hardened up much thinking about complex systems.
- Specific focus on networks that are large-scale, sparse, natural or people-made, evolving and dynamic, and (crucially) measurable.
- Three main (blurred) categories:
 - 1. Physical (e.g., river networks),
 - 2. Interactional (e.g., social networks),
 - 3. Abstract (e.g., thesauri).
- To solve network problems: "Follow the edges."

More Allegations:

Sometimes the map is not the territory because the territory does not exist.

"But it might one day!" yelled Captain Survivor Bias IV while holding up two pineapples to gauge the distance between waves.

And the mapper is never the map.

(Scientific truths shouldn't be named after individuals.)

Rather silly but great example of real science:

"How Cats Lap: Water Uptake by Felis catus" Reis et al., Science, 2010.

A Study of Cat Lapping

Adult cats and dogs are unable to create suction in their mouths and must use their tongues to drink. A dog will scoop up liquid with the back of its tongue, but a cat will only touch the surface with the smooth tip of its tongue and pull a column of liquid into its mouth.

Liquid sticks

to smooth tip.

Warnings:

- 🙈 Networks aren't everything.
- Famous models of networks aren't everything in networks.
- Mathematical tractability \(\neq \) meaningfulness or viable existence in reality
- Even when networks are core to a system, the best level of analysis may involve some scale of grouping/averaging.
- Groups, groups, groups.
- $\red > \Lambda$ And pyramids (\sim hierarchies)

The absolute basics:

Modern basic science in three steps:

- Find interesting/meaningful/important phenomena, optionally involving spectacular amounts of data.
- 2. Describe what you see.
- 3. Explain it.

If you succeed at 1–3:

- 4. Create.
- 5. Share.

Always:

6. Be good people.
