There are other 'heavy-tailed' distributions:

1. The Log-normal distribution ↗

$$P(x) = \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

2. Weibull distributions ↗

$$P(x)dx = \frac{k}{\lambda} \left(\frac{x}{\lambda}\right)^{\mu-1} e^{-(x/\lambda)^\mu} dx$$

CCDF = stretched exponential ↗.

3. Also: Gamma distribution ↗, Erlang distribution ↗, and more.

The lognormal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

-  $\ln x$ is distributed according to a normal distribution with mean μ and variance σ .
-  Appears in economics and biology where growth increments are distributed normally.

Lognormals

Empirical Confusability
Random Multiplicative
Growth Model
Random Growth with
Variable Lifespan

 Standard form reveals the mean μ and variance σ^2 of the underlying normal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

 For lognormals:

$$\mu_{\text{lognormal}} = e^{\mu + \frac{1}{2}\sigma^2}, \quad \text{median}_{\text{lognormal}} = e^{\mu},$$

$$\sigma_{\text{lognormal}} = (e^{\sigma^2} - 1)e^{2\mu + \sigma^2}, \quad \text{mode}_{\text{lognormal}} = e^{\mu - \sigma^2}.$$

 All moments of lognormals are **finite**.

Derivation from a normal distribution

Take Y as distributed normally:

$$P(y)dy = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(y-\mu)^2}{2\sigma^2}\right) dy$$

Lognormals

Empirical Confusability
Random Multiplicative
Growth Model
Random Growth with
Variable Lifespan

References

Set $Y = \ln X$:

Transform according to $P(x)dx = P(y)dy$:

$$\frac{dy}{dx} = 1/x \Rightarrow dy = dx/x$$

$$\Rightarrow P(x)dx = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) dx$$

Confusion between lognormals and pure power laws

PoCS
@pocsvox

Lognormals and friends

Near agreement
over four orders
of magnitude!

For lognormal (blue), $\mu = 0$ and $\sigma = 10$.

For power law (red), $\gamma = 1$ and $c = 0.03$.

What's happening:

$$\begin{aligned}\ln P(x) &= \ln \left\{ \frac{1}{x\sqrt{2\pi}\sigma} \exp \left(-\frac{(\ln x - \mu)^2}{2\sigma^2} \right) \right\} \\ &= -\ln x - \ln\sqrt{2\pi}\sigma - \frac{(\ln x - \mu)^2}{2\sigma^2}\end{aligned}$$

$$= -\frac{1}{2\sigma^2} (\ln x)^2 + \left(\frac{\mu}{\sigma^2} - 1 \right) \ln x - \ln\sqrt{2\pi}\sigma - \frac{\mu^2}{2\sigma^2}.$$

If the first term is relatively small,

$$\boxed{\ln P(x) \sim -\left(1 - \frac{\mu}{\sigma^2}\right) \ln x + \text{const.}} \Rightarrow \boxed{\gamma = 1 - \frac{\mu}{\sigma^2}}$$

Lognormals

Empirical Confusability
Random Multiplicative
Growth Model
Random Growth with
Variable Lifespan

References

 If $\mu < 0, \gamma > 1$ which is totally cool.

 If $\mu > 0, \gamma < 1$, not so much.

 If $\sigma^2 \gg 1$ and $\mu,$

$$\ln P(x) \sim -\ln x + \text{const.}$$

 Expect -1 scaling to hold until $(\ln x)^2$ term becomes significant compared to $(\ln x)$:

$$-\frac{1}{2\sigma^2} (\ln x)^2 \simeq 0.05 \left(\frac{\mu}{\sigma^2} - 1 \right) \ln x$$

$$\Rightarrow \log_{10} x \lesssim 0.05 \times 2(\sigma^2 - \mu) \log_{10} e \simeq 0.05(\sigma^2 - \mu)$$

 \Rightarrow If you find a -1 exponent,
you may have a lognormal distribution...

Generating lognormals:

Random multiplicative growth:

$$x_{n+1} = rx_n$$

where $r > 0$ is a random growth variable

(Shrinkage is allowed)

In log space, growth is by addition:

$$\ln x_{n+1} = \ln r + \ln x_n$$

$\Rightarrow \ln x_n$ is normally distributed

$\Rightarrow x_n$ is lognormally distributed

Lognormals or power laws?

- 🧱 Gibrat [2] (1931) uses preceding argument to explain lognormal distribution of firm sizes ($\gamma \approx 1$).
- 🧱 But Robert Axtell [1] (2001) shows a power law fits the data very well with $\gamma = 2$, not $\gamma = 1$ (!)
- 🧱 Problem of data censusing (missing small firms).

- 🧱 One piece in Gibrat's model seems okay empirically: Growth rate r appears to be independent of firm size. [1].

An explanation

 Axtel cites Malcai et al.'s (1999) argument ^[5] for why power laws appear with exponent $\gamma \simeq 2$

 The set up: N entities with size $x_i(t)$

 Generally:

$$x_i(t+1) = rx_i(t)$$

where r is drawn from some happy distribution

 Same as for lognormal but one extra piece.

 Each x_i cannot drop too low with respect to the other sizes:

$$x_i(t+1) = \max(rx_i(t), c \langle x_i \rangle)$$

Some math later...

Insert question from assignment 7 

Find $P(x) \sim x^{-\gamma}$

where γ is implicitly given by

$$N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[\frac{(c/N)^{\gamma-1} - 1}{(c/N)^{\gamma-1} - (c/N)} \right]$$

N = total number of firms.

Now, if $c/N \ll 1$ and $\gamma > 2$ $N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[\frac{-1}{-(c/N)} \right]$

Which gives $\gamma \sim 1 + \frac{1}{1 - c}$

Groovy... c small $\Rightarrow \gamma \simeq 2$

The second tweak

Ages of firms/people/... may not be the same

- Allow the number of updates for each size x_i to vary
- Example: $P(t)dt = ae^{-at}dt$ where $t = \text{age}$.
- Back to no bottom limit: each x_i follows a lognormal
- Sizes are distributed as ^[6]

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln x - \mu)^2}{2t}\right) dt$$

(Assume for this example that $\sigma \sim t$ and $\mu = \ln m$)

- Now averaging different lognormal distributions.

Averaging lognormals

$$P(x) = \int_{t=0}^{\infty} a e^{-at} \frac{1}{x \sqrt{2\pi t}} \exp\left(-\frac{(\ln \frac{x}{m})^2}{2t}\right) dt$$

Insert fabulous calculation (team is spared).

Some enjoyable suffering leads to:

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda} (\ln \frac{x}{m})^2}$$

Lognormals

Empirical Confusability
Random Multiplicative
Growth Model
Random Growth with
Variable Lifespan

References

The second tweak

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda(\ln \frac{x}{m})^2}}$$

Depends on sign of $\ln \frac{x}{m}$, i.e., whether $\frac{x}{m} > 1$ or $\frac{x}{m} < 1$.

$$P(x) \propto \begin{cases} x^{-1+\sqrt{2\lambda}} & \text{if } \frac{x}{m} < 1 \\ x^{-1-\sqrt{2\lambda}} & \text{if } \frac{x}{m} > 1 \end{cases}$$

'Break' in scaling (not uncommon)

Double-Pareto distribution 

First noticed by Montroll and Shlesinger ^[7, 8]

Summary of these exciting developments:

PoCS
@pocsvox

Lognormals and
friends

-  Lognormals and power laws can be **awfully** similar
-  Random Multiplicative Growth leads to lognormal distributions
-  Enforcing a minimum size leads to a power law tail
-  With no minimum size but a distribution of lifetimes, the double Pareto distribution appears
-  **Take-home message:** Be careful out there...
