Scale-free
networks

 Networks with power-law degree distributions have become known as **scale-free** networks.

 Scale-free refers specifically to the **degree distribution** having a **power-law decay** in its tail:

$$P_k \sim k^{-\gamma} \text{ for 'large' } k$$

 One of the seminal works in complex networks:

"Emergence of scaling in random networks" 

Barabási and Albert,
Science, **286**, 509–511, 1999. [2]

Times cited: ~ 23,532  (as of October 8, 2015)

 Somewhat misleading nomenclature...

Scale-free
networks

- Scale-free networks are **not fractal** in any sense.
- Usually talking about networks whose links are **abstract, relational, informational, ...**(non-physical)
- Primary example: hyperlink network of the Web
- Much arguing about whether or networks are 'scale-free' or not...

Scale-free
networks

The big deal:

- 🧱 We move beyond describing networks to finding **mechanisms** for why certain networks are the way they are.

A big deal for scale-free networks:

- 🧱 How does the exponent γ depend on the mechanism?
- 🧱 Do the mechanism details matter?

BA model

PoCS
@pocsvox

Scale-free
networks

- 🧱 Barabási-Albert model = BA model.
- 🧱 Key ingredients:
 - Growth** and **Preferential Attachment (PA)**.
- 🧱 **Step 1**: start with m_0 disconnected nodes.
- 🧱 **Step 2**:
 1. **Growth**—a new node appears at each time step $t = 0, 1, 2, \dots$
 2. Each new node makes m links to nodes already present.
 3. **Preferential attachment**—Probability of connecting to i th node is $\propto k_i$.
- 🧱 In essence, we have a **rich-gets-richer** scheme.
- 🧱 Yes, we've seen this all before in Simon's model.

 **Definition:** A_k is the attachment kernel for a node with degree k .

 For the original model:

$$A_k = k$$

 **Definition:** $P_{\text{attach}}(k, t)$ is the attachment probability.

 For the original model:

$$P_{\text{attach}}(\text{node } i, t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{\max}(t)} k N_k(t)}$$

where $N(t) = m_0 + t$ is # nodes at time t
and $N_k(t)$ is # degree k nodes at time t .

Approximate analysis

- When $(N + 1)$ th node is added, the expected increase in the degree of node i is

$$E(k_{i,N+1} - k_{i,N}) \simeq m \frac{k_{i,N}}{\sum_{j=1}^{N(t)} k_j(t)}.$$

- Assumes probability of being connected to is **small**.
- Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.
- Approximate $k_{i,N+1} - k_{i,N}$ with $\frac{d}{dt}k_{i,t}$:

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where $t = N(t) - m_0$.

Deal with denominator: each added node brings m new edges.

$$\therefore \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

The node degree equation now simplifies:

$$\frac{d}{dt} k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = m \frac{k_i(t)}{2mt} = \frac{1}{2t} k_i(t)$$

Rearrange and solve:

$$\frac{dk_i(t)}{k_i(t)} = \frac{dt}{2t} \Rightarrow \boxed{k_i(t) = c_i t^{1/2}}$$

Next find c_i ...

 Know i th node appears at time

$$t_{i,\text{start}} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

 So for $i > m_0$ (exclude initial nodes), we must have

$$k_i(t) = m \left(\frac{t}{t_{i,\text{start}}} \right)^{1/2} \quad \text{for } t \geq t_{i,\text{start}}.$$

 All node degrees grow as $t^{1/2}$ but later nodes have larger $t_{i,\text{start}}$ which **flattens out** growth curve.

 First-mover advantage: Early nodes do **best**.

 Clearly, a Ponzi scheme .

We are already at the Zipf distribution:

 Degree of node i is the size of the i th ranked node:

$$k_i(t) = m \left(\frac{t}{t_{i,\text{start}}} \right)^{1/2} \quad \text{for } t \geq t_{i,\text{start}}.$$

 From before:

$$t_{i,\text{start}} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

so $t_{i,\text{start}} \sim i$ which is the rank.

 We then have:

$$k_i \propto i^{-1/2} = i^{-\alpha}.$$

 Our connection $\alpha = 1/(\gamma - 1)$ or $\gamma = 1 + 1/\alpha$ then gives

$$\gamma = 1 + 1/(1/2) = 3.$$

Degree distribution

So what's the **degree distribution** at time t ?

Use fact that birth time for added nodes is distributed uniformly between time 0 and t :

$$\Pr(t_{i,\text{start}}) dt_{i,\text{start}} \simeq \frac{dt_{i,\text{start}}}{t}$$

Also use

$$k_i(t) = m \left(\frac{t}{t_{i,\text{start}}} \right)^{1/2} \Rightarrow t_{i,\text{start}} = \frac{m^2 t}{k_i(t)^2}$$

Transform variables—Jacobian:

$$\frac{dt_{i,\text{start}}}{dk_i} = -2 \frac{m^2 t}{k_i(t)^3}$$

Degree distribution

$$\Pr(k_i)dk_i = \Pr(t_{i,\text{start}})dt_{i,\text{start}}$$

$$= \Pr(t_{i,\text{start}})dk_i \left| \frac{dt_{i,\text{start}}}{dk_i} \right|$$

$$= \frac{1}{t} dk_i 2 \frac{m^2 t}{k_i(t)^3}$$

$$= 2 \frac{m^2}{k_i(t)^3} dk_i$$

$$\propto k_i^{-3} dk_i.$$

Degree distribution

- 🧱 We thus have a very specific prediction of $\Pr(k) \sim k^{-\gamma}$ with $\gamma = 3$.
- 🧱 Typical for real networks: $2 < \gamma < 3$.
- 🧱 Range true more generally for events with size distributions that have power-law tails.
- 🧱 $2 < \gamma < 3$: finite mean and 'infinite' variance (wild)
- 🧱 In practice, $\gamma < 3$ means variance is governed by upper cutoff.
- 🧱 $\gamma > 3$: finite mean and variance (mild)

Preferential attachment

PoCS
@pocsvox

Scale-free
networks

Let's look at preferential attachment (PA) a little more closely.

PA implies arriving nodes have **complete knowledge** of the existing network's degree distribution.

For example: If $P_{\text{attach}}(k) \propto k$, we need to determine the constant of proportionality.

We need to know what everyone's degree is...

PA is \therefore an **outrageous** assumption of node capability.

But a **very simple mechanism** saves the day...

Preferential attachment through randomness

- Instead of attaching preferentially, allow new nodes to attach randomly.
- Now add an **extra step**: new nodes then connect to some of their friends' friends.
- Can also do this **at random**.
- Assuming the existing network is random, we know probability of a **random friend** having degree k is

$$Q_k \propto kP_k$$

- So **rich-gets-richer** scheme can now be seen to work in a natural way.

Fooling with the mechanism:

- 2001: Krapivsky & Redner (KR) [4] explored the **general attachment kernel**:

$$\Pr(\text{attach to node } i) \propto A_k = k_i^\nu$$

where A_k is the attachment kernel and $\nu > 0$.

- KR also looked at changing the details of the attachment kernel.
- KR model will be fully studied in CoNKS.

Generalized model

 We'll follow KR's approach using rate equations .

 Here's the set up:

$$\frac{dN_k}{dt} = \frac{1}{A} [A_{k-1}N_{k-1} - A_k N_k] + \delta_{k1}$$

where N_k is the number of nodes of degree k .

1. One node with one link is added per unit time.
2. The **first term** corresponds to degree $k - 1$ nodes becoming degree k nodes.
3. The **second term** corresponds to degree k nodes becoming degree $k - 1$ nodes.
4. A is the correct normalization (coming up).
5. Seed with some initial network (e.g., a connected pair)
6. Detail: $A_0 = 0$

Scale-free networks

Generalized model

-  In general, probability of attaching to a **specific node** of degree k at time t is

$$\Pr(\text{attach to node } i) = \frac{A_k}{A(t)}$$

where $A(t) = \sum_{k=1}^{\infty} A_k N_k(t)$.

-  E.g., for BA model, $A_k = k$ and $A = \sum_{k=1}^{\infty} k N_k(t)$.

-  For $A_k = k$, we have

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) = 2t$$

since one edge is being added per unit time.

-  Detail: we are ignoring initial seed network's edges.

Generalized model

 So now

$$\frac{dN_k}{dt} = \frac{1}{A} [A_{k-1}N_{k-1} - A_k N_k] + \delta_{k1}$$

becomes

$$\frac{dN_k}{dt} = \frac{1}{2t} [(k-1)N_{k-1} - kN_k] + \delta_{k1}$$

 As for BA method, look for steady-state growing solution: $N_k = n_k t$.

 We replace dN_k/dt with $dn_k t/dt = n_k$.

 We arrive at a difference equation:

$$n_k = \frac{1}{2t} [(k-1)n_{k-1}t - kn_k t] + \delta_{k1}$$

Universality?

- As expected, we have the same result as for the BA model:

$$N_k(t) = n_k(t)t \propto k^{-3}t \text{ for large } k.$$

- Now: what happens if we start playing around with the attachment kernel A_k ?
- Again, we're asking if the result $\gamma = 3$ universal ↗?
- KR's natural modification: $A_k = k^\nu$ with $\nu \neq 1$.
- But we'll first explore a more subtle modification of A_k made by Krapivsky/Redner^[4]
- Keep A_k **linear** in k but tweak details.
- Idea:** Relax from $A_k = k$ to $A_k \sim k$ as $k \rightarrow \infty$.

Universality?

 Recall we used the normalization:

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) \simeq 2t \text{ for large } t.$$

 We now have

$$A(t) = \sum_{k'=1}^{\infty} A_{k'} N_{k'}(t)$$

where we only know the asymptotic behavior of A_k .

 We assume that $A = \mu t$

 We'll find μ later and make sure that our assumption is consistent.

 As before, also assume $N_k(t) = n_k t$.

Universality?

 For $A_k = k$ we had

$$n_k = \frac{1}{2} [(k-1)n_{k-1} - kn_k] + \delta_{k1}$$

 This now becomes

$$n_k = \frac{1}{\mu} [A_{k-1}n_{k-1} - A_k n_k] + \delta_{k1}$$

$$\Rightarrow (A_k + \mu)n_k = A_{k-1}n_{k-1} + \mu\delta_{k1}$$

 Again two cases:

$$k = 1 : n_1 = \frac{\mu}{\mu + A_1}; \quad k > 1 : n_k = n_{k-1} \frac{A_{k-1}}{\mu + A_k}.$$

Universality?

PoCS
@pocsvox
Scale-free
networks

Time for pure excitement: Find **asymptotic behavior** of n_k given $A_k \rightarrow k$ as $k \rightarrow \infty$.

For large k , we find:

$$n_k = \frac{\mu}{A_k} \prod_{j=1}^k \frac{1}{1 + \frac{\mu}{A_j}} \propto k^{-\mu-1}$$

Since μ depends on A_k , **details matter...**

Universality?

Now we need to find μ .

Our assumption again: $A = \mu t = \sum_{k=1}^{\infty} N_k(t) A_k$

Since $N_k = n_k t$, we have the simplification
$$\mu = \sum_{k=1}^{\infty} n_k A_k$$

Now substitute in our expression for n_k :

$$1\mu = \sum_{k=1}^{\infty} \frac{\mu}{A_k} \prod_{j=1}^k \frac{1}{1 + \frac{\mu}{A_j}}$$

Closed form expression for μ .

We can solve for μ in some cases.

Our assumption that $A = \mu t$ looks to be not too horrible.

Consider tunable $A_1 = \alpha$ and $A_k = k$ for $k \geq 2$.

Again, we can find $\gamma = \mu + 1$ by finding μ .

Closed form expression for μ :

$$\frac{\mu}{\alpha} = \sum_{k=2}^{\infty} \frac{\Gamma(k+1)\Gamma(2+\mu)}{\Gamma(k+\mu+1)}$$

#mathisfun

$$\mu(\mu - 1) = 2\alpha \Rightarrow \mu = \frac{1 + \sqrt{1 + 8\alpha}}{2}.$$

Since $\gamma = \mu + 1$, we have

$$0 \leq \alpha < \infty \Rightarrow 2 \leq \gamma < \infty$$

Craziness...

Sublinear attachment kernels

 Rich-get-somewhat-richer:

$$A_k \sim k^\nu \text{ with } 0 < \nu < 1.$$

 General finding by Krapivsky and Redner: [4]

$$n_k \sim k^{-\nu} e^{-c_1 k^{1-\nu}} + \text{correction terms.}$$

 Stretched exponentials (truncated power laws).

 aka Weibull distributions.

 **Universality**: now details of kernel **do not** matter.

 Distribution of degree is universal providing $\nu < 1$.

Details:

 For $1/2 < \nu < 1$:

$$n_k \sim k^{-\nu} e^{-\mu \left(\frac{k^{1-\nu} - 2^{1-\nu}}{1-\nu} \right)}$$

 For $1/3 < \nu < 1/2$:

$$n_k \sim k^{-\nu} e^{-\mu \frac{k^{1-\nu}}{1-\nu} + \frac{\mu^2}{2} \frac{k^{1-2\nu}}{1-2\nu}}$$

 And for $1/(r+1) < \nu < 1/r$, we have r pieces in exponential.

Scale-free
networks

 Rich-get-much-richer:

$$A_k \sim k^\nu \text{ with } \nu > 1.$$

 Now a **winner-take-all** mechanism.

 One single node ends up being connected to almost all other nodes.

 For $\nu > 2$, all but a finite # of nodes connect to one node.

Overview Key Points for Models of Networks:

- Obvious connections with the vast extant field of graph theory.
- But focus on dynamics is more of a physics/stat-mech/comp-sci flavor.
- Two main areas of focus:
 - Description:** Characterizing very large networks
 - Explanation:** Micro story \Rightarrow Macro features
- Some essential structural aspects are understood: degree distribution, clustering, assortativity, group structure, overall structure,...
- Still much work to be done, especially with respect to dynamics... **#excitement**
