Many sources, many sinks

How do we distribute sources?

- Focus on 2-d (results generalize to higher dimensions).
- Sources = hospitals, post offices, pubs, ...
- Key problem: How do we cope with uneven population densities?
- Obvious: if density is uniform then sources are best distributed uniformly.
- Which lattice is optimal? The hexagonal lattice
- Q2: Given population density is uneven, what do we do?
- We'll follow work by Stephan (1977, 1984) [4, 5], Gastner and Newman (2006) [2], Um *et al.* (2009) [6], and work cited by them.

Solidifying the basic problem

- Given a region with some population distribution ρ , most likely uneven.
- Given resources to build and maintain N facilities.
- \bigcirc O: How do we locate these N facilities so as to minimize the average distance between an individual's residence and the nearest facility?

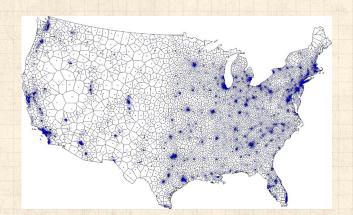

"Optimal design of spatial distribution networks" (2"

Gastner and Newman, Phys. Rev. E, **74**, 016117, 2006. [2]

Approximately optimal location of 5000 facilities.

Based on 2000 Census data.

artograms

A reasonable derivation
Global redistribution

Consider a region of area A and population P with a single functional center that everyone needs to access every day.

Build up a general cost function based on time expended to access and maintain center.

Write average travel distance to center as \bar{d} and assume average speed of travel is \bar{v} .

Assume isometry: average travel distance \bar{d} will be on the length scale of the region which is $\sim A^{1/2}$

Average time expended per person in accessing facility is therefore

$$\bar{d}/\bar{v} = cA^{1/2}/\bar{v}$$

where c is an unimportant shape factor.

PoCS @pocsvox

Optimal Supply Networks III

Distributed Sources

Size-density law

A reasonable derivation Global redistribution Public versus Private

Next assume facility requires regular maintenance (person-hours per day).

& Call this quantity τ .

All If burden of mainenance is shared then average cost per person is τ/P where P = population.

Important assumption: uniform density.

Total average time cost per person:

$$T = \bar{d}/\bar{v} + \tau/(\rho_{\sf pop}A) = cA^{1/2}/\bar{v} + \tau/(\rho_{\sf pop}A).$$

 $\red {\Bbb S}$ Now Minimize with respect to $A \dots$

Optimal Supply Networks III

Distributed Sources

Size-density law

A reasonable derivation Global redistribution Public versus Private

Differentiating ...

$$\begin{split} \frac{\partial T}{\partial A} &= \frac{\partial}{\partial A} \left(c A^{1/2}/\bar{v} + \tau/(\rho_{\mathsf{pop}} A) \right) \\ &= \frac{c}{2\bar{v} A^{1/2}} - \frac{\tau}{\rho_{\mathsf{pop}} A^2} = 0 \end{split}$$

Rearrange:

$$A = \left(rac{2ar{v} au}{c
ho_{\mathsf{pop}}}
ight)^{2/3} \propto
ho_{\mathsf{pop}}^{-2/3}$$

 \clubsuit # facilities per unit area ρ_{fac} :

$$ho_{
m fac} \propto A^{-1} \propto
ho_{
m pop}^{2/3}$$

Diffusion-based cartograms:

- ldea of cartograms is to distort areas to more accurately represent some local density $\rho_{\rm pop}$ (e.g. population).
- Many methods put forward—typically involve some kind of physical analogy to spreading or repulsion.
- Algorithm due to Gastner and Newman (2004) [1] is based on standard diffusion:

$$\nabla^2 \rho_{\mathsf{pop}} - \frac{\partial \rho_{\mathsf{pop}}}{\partial t} = 0.$$

- Allow density to diffuse and trace the movement of individual elements and boundaries.
- $\ref{Diffusion}$ Diffusion is constrained by boundary condition of surrounding area having density $\bar{\rho}_{pop}$.

Deriving the optimal source distribution:

Assume given a fixed population density ρ_{pop} defined on a spatial region $\Omega.$

$$F(\{\vec{x}_1,\dots,\vec{x}_n\}) = \int_{\Omega} \frac{\rho_{\mathsf{pop}}(\vec{x}) \min_i ||\vec{x} - \vec{x}_i|| \mathrm{d}\vec{x} \,.$$

- Also known as the p-median problem.
- Not easy ...in fact this one is an NP-hard problem. [2]
- Approximate solution originally due to Gusein-Zade [3].

PoCS @pocsvox

Optimal Supply Networks III

Distributed Sources

Size-density law Cartograms A reasonable derivation

Global redistribution Public versus Private

Approximations:

Define $A(\vec{x})$ as the area of the Voronoi cell containing \vec{x} .

As per Stephan's calculation, estimate typical distance from \vec{x} to the nearest source (say i) as

$$c_i A(\vec{x})^{1/2}$$

where c_i is a shape factor for the ith Voronoi cell.

 $\begin{cases} \& \end{cases}$ Approximate c_i as a constant c.

PoCS @pocsvox

Optimal Supply Networks III

Distributed Sources

Size-density law Cartograms

A reasonable derivation Global redistribution

Carrying on:

The cost function is now

$$F = c \int_{\Omega} \rho_{\rm pop}(\vec{x}) A(\vec{x})^{1/2} \mathrm{d}\vec{x} \,. \label{eq:F_pop}$$

- We also have that the constraint that Voronoi cells divide up the overall area of Ω : $\sum_{i=1}^{n} A(\vec{x}_i) = A_{\Omega}$.
- Sneakily turn this into an integral constraint:

$$\int_{\Omega} \frac{\mathrm{d}\vec{x}}{A(\vec{x})} = n.$$

- $\red{solution}$ Within each cell, $A(\vec{x})$ is constant.
- & So ...integral over each of the n cells equals 1.

Optimal Supply Networks III

Distributed Sources

Size-density law Cartograms

A reasonable derivation

Public versus Priva

Now a Lagrange multiplier story:

 \S By varying $\{\vec{x}_1, \dots, \vec{x}_n\}$, minimize

Pocs @pocsvox

Optimal Supply Networks III

$$G(A) = c \int_{\Omega} \rho_{\mathsf{pop}}(\vec{x}) A(\vec{x})^{1/2} \mathrm{d}\vec{x} - \lambda \left(n - \int_{\Omega} \left[A(\vec{x}) \right]^{-1} \mathrm{d}\vec{x} \right) \underset{\text{Size-density law}}{\mathsf{Distributed}} \int_{\mathsf{Size-density law}} \mathrm{d}\vec{x} d\vec{x} = 0$$

A reasonable derivation

References

- I Can Haz Calculus of Variations ??
- & Compute $\delta G/\delta A$, the functional derivative \Box of the functional G(A).
- This gives

$$\int_{\Omega} \left[\frac{c}{2} \rho_{\mathsf{pop}}(\vec{x}) A(\vec{x})^{-1/2} - \lambda \left[A(\vec{x}) \right]^{-2} \right] \mathrm{d}\vec{x} \, = 0.$$

Setting the integrand to be zilch, we have:

$$\label{eq:rhopop} \rho_{\mathsf{pop}}(\vec{x}) = 2\lambda c^{-1}A(\vec{x})^{-3/2}.$$

Now a Lagrange multiplier story:

Rearranging, we have

$$A(\vec{x}) = (2\lambda c^{-1})^{2/3} \rho_{\mathsf{pop}}^{-2/3}.$$

- $\ref{eq:property}$ Finally, we indentify $1/A(\vec{x})$ as $ho_{
 m fac}(\vec{x})$, an approximation of the local source density.
- $\red{\$}$ Substituting $ho_{\mathsf{fac}} = 1/A$, we have

$$ho_{\mathrm{fac}}(\vec{x}) = \left(rac{c}{2\lambda}
ho_{\mathrm{pop}}
ight)^{2/3}.$$

& Normalizing (or solving for λ):

$$\rho_{\rm fac}(\vec{x}) = n \frac{[\rho_{\rm pop}(\vec{x})]^{2/3}}{\int_{\Omega} [\rho_{\rm pop}(\vec{x})]^{2/3} {\rm d}\vec{x}} \propto [\rho_{\rm pop}(\vec{x})]^{2/3}.$$

Cartograms

A reasonable derivation Global redistribution Public versus Private

Global redistribution networks

One more thing:

How do we best redistribute mail? People?

How do we get beer to the pubs?

Gastner and Newman model: cost is a function of basic maintenance and travel time:

$$C_{\mathsf{maint}} + \gamma C_{\mathsf{travel}}.$$

Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance ℓ_{ij} and number of legs to journey:

$$(1-\delta)\ell_{ij} + \delta(\#\mathsf{hops}).$$

& When $\delta = 1$, only number of hops matters.

Public versus private facilities

Beyond minimizing distances:

- "Scaling laws between population and facility densities" by Um et al., Proc. Natl. Acad. Sci., 2009. [6]
- Um et al. find empirically and argue theoretically that the connection between facility and population density

$$\rho_{\rm fac} \propto \rho_{\rm pop}^{\alpha}$$

does not universally hold with $\alpha = 2/3$.

- Two idealized limiting classes:
 - 1. For-profit, commercial facilities: $\alpha = 1$;
 - 2. Pro-social, public facilities: $\alpha = 2/3$.
- Um et al. investigate facility locations in the United States and South Korea.

Public versus private facilities: the story

So what's going on?

Commercial institutions seek to maximize the number of visitors.

 n_i = population of the *i*th cell;

 $\langle r_i \rangle$ = the average travel distance to the ith facility.

 A_i = area of ith cell (s_i in Um et al. A_i in Um et al. A_i

Objective function to maximize for a facility (highly constructed):

$$v_i = n_i \langle r_i \rangle^\beta \text{ with } 0 \leq \beta \leq 1.$$

 $\beta = 0$: purely commercial.

 $\beta = 1$: purely social.

Either proceeding as per the Gastner-Newman-Gusein-Zade calculation or, as Um et al. do, observing that the cost for each cell should be the same, we have:

$$\label{eq:rhofac} \begin{split} \rho_{\rm fac}(\vec{x}) &= n \frac{[\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)}}{\int_{\Omega} [\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)} \mathrm{d}\vec{x}} \propto [\rho_{\rm pop}(\vec{x})]^{2/(\beta+2)}. \end{split}$$

 β For $\beta = 0$, $\alpha = 1$: commercial scaling is linear.

 \Re For $\beta = 1$, $\alpha = 2/3$: social scaling is sublinear.
