Two of the many things we struggle with cognitively:

1. Probability.

Ex. The Monty Hall Problem.

Ex. Daughter/Son born on Tuesday. (see next two slides; Wikipedia entry here .)

2. Logarithmic scales.

On counting and logarithms:

Later: Benford's Law .

Also to be enjoyed: the magnificence of the Dunning-Kruger effect

Homo probabilisticus?

The set up:

A parent has two children.

Simple probability question:

What is the probability that both children are girls?

The next set up:

A parent has two children.

We know one of them is a girl.

The next probabilistic poser:

What is the probability that both children are girls?

Try this one:

A parent has two children.

We know one of them is a girl born on a Tuesday.

Simple question #3:

What is the probability that both children are girls?

Last:

🙈 A parent has two children.

We know one of them is a girl born on December 31.

And ...

What is the probability that both children are girls?

Let's test our collective intuition:

Money ≡ Belief

Two questions about wealth distribution in the United States:

- Please estimate the percentage of all wealth owned by individuals when grouped into quintiles.
- 2. Please estimate what you believe each quintile should own, ideally.
- 3. Extremes: 100, 0, 0, 0, 0 and 20, 20, 20, 20, 20.

Zipf's law

 $Zipf \Leftrightarrow CCDF$

The sizes of many systems' elements appear to obey an inverse power-law size distribution:

$$P({\rm Size} = x) \sim c\, x^{-\gamma}$$

$$\text{ where } \quad 0 < x_{\min} < x < x_{\max} \quad \text{and} \quad \gamma > 1.$$

Negative linear relationship in log-log space:

$$\log_{10}P(x) = \log_{10}c - \gamma \mathrm{log}_{10}x$$

We use base 10 because we are good people.

CCDFs

Zipf's law

 $\mathsf{Zipf} \Leftrightarrow \mathsf{CCDF}$

Size distributions:

Many systems have discrete sizes k:

- Word frequency
- Node degree in networks: # friends, # hyperlinks, etc.
- 🚓 # citations for articles, court decisions, etc.

$$P(k) \sim c \, k^{-\gamma} \label{eq:problem}$$
 where $k_{\rm min} \leq k \leq k_{\rm max}$

- Again, typically a description of distribution's tail.

The statistics of surprise:

From: "Quake Moves Japan Closer to U.S. and Alters Earth's Spin" by Kenneth Chang, March 13, 2011, NYT:

What is perhaps most surprising about the Japan earthquake is how misleading history can be. In the past 300 years, no earthquake nearly that large—nothing larger than magnitude eight—had struck in the Japan subduction zone. That, in turn, led to assumptions about how large a tsunami might strike the coast.'

"It did them a giant disservice," said Dr. Stein of the geological survey. That is not the first time that the earthquake potential of a fault has been underestimated. Most geophysicists did not think the Sumatra fault could generate a magnitude 9.1 earthquake, ...'

Devilish power-law size distribution details:

PoCS @pocsvox

Power-Law Size Distributions

Exhibit A:

Siven $P(x) = cx^{-\gamma}$ with $0 < x_{min} < x < x_{max}$, the mean is $(\gamma \neq 2)$:

$$\langle x \rangle = \frac{c}{2-\gamma} \left(x_{\rm max}^{2-\gamma} - x_{\rm min}^{2-\gamma} \right). \label{eq:expansion}$$

Insert question from assignment 2 2

Definition

Examples

Wild vs. Mild

CCDFs

Zipf's law

 $\mathsf{Zipf} \Leftrightarrow \mathsf{CCDF}$

And in general ...

Moments:

All moments depend only on cutoffs.

No internal scale that dominates/matters.

& Compare to a Gaussian, exponential, etc.

For many real size distributions: $2 < \gamma < 3$

mean is finite (depends on lower cutoff)

 $\delta \sigma^2$ = variance is 'infinite' (depends on upper cutoff)

Width of distribution is 'infinite'

 $\ \ \, \& \ \ \,$ If $\gamma>3$, distribution is less terrifying and may be easily confused with other kinds of distributions.

Insert question from assignment 3 🗷

Power-Law Size Distributions

Our Intuition

Definition

Examples

Wild vs. Mild

CCDFs

Zipf's law

 $\mathsf{Zipf} \Leftrightarrow \mathsf{CCDF}$

Moments

Standard deviation is a mathematical convenience:

- & Variance is nice analytically ...
- Another measure of distribution width:

Mean average deviation (MAD) = $\langle |x - \langle x \rangle| \rangle$

For a pure power law with $2 < \gamma < 3$:

 $\langle |x - \langle x \rangle| \rangle$ is finite.

- 🙈 But MAD is mildly unpleasant analytically ...
- & We still speak of infinite 'width' if $\gamma < 3$.

PoCS @pocsvox

Power-Law Size Distributions

CCDFs

Zipf's law

 $\mathsf{Zipf} \Leftrightarrow \mathsf{CCDF}$

How sample sizes grow ...

Given $P(x) \sim cx^{-\gamma}$:

 $\ensuremath{ \begin{subarray}{l} \ensuremath{ \begin{subarray}{l} \ensuremath{ \begin{subarray}{l} \ensuremath{ \ensuremath{ \ensuremath{ \begin{subarray}{l} \ensuremath{ \$

$$x_1 \gtrsim c' n^{1/(\gamma-1)}$$

Sampling from a finite-variance distribution gives a much slower growth with n.

 \clubsuit e.g., for $P(x) = \lambda e^{-\lambda x}$, we find

$$x_1 \gtrsim \frac{1}{\lambda} \ln n.$$

Insert question from assignment 4 🗹 Insert question from assignment 6 🖸

 1 Later, we see that the largest sample grows as n^{ρ} where ρ is the Zipf exponent

CDFs

Zipf's law
Zipf ⇔ CCDF

Observe:

 $\ref{eq:second}$ If an object has size x_r , then $NP_{\geq}(x_r)$ is its rank r.

备 So

$$x_r \propto r^{-\alpha} = (NP_{\geq}(x_r))^{-\alpha}$$

$$\propto x_r^{-(\gamma-1)(-lpha)}$$
 since $P_>(x) \sim x^{-(\gamma-1)}$.

We therefore have $1 = -(\gamma - 1)(-\alpha)$ or:

$$\alpha = \frac{1}{\gamma - 1}$$

 $\ \, \hbox{$\stackrel{<}{{}_{\sim}}$} \,$ A rank distribution exponent of $\alpha=1$ corresponds to a size distribution exponent $\gamma=2.$

"Zipf's Law in the Popularity Distribution of Chess Openings" 🗗

Blasius and Tönjes, Phys. Rev. Lett., **103**, 218701, 2009. [3]

- & Examined all games of varying game depth d in a set of chess databases.
- n = popularity = how many times a specific game path appears in databases.
- $\Re S(n;d)$ = number of depth d games with popularity n.
- Show "the frequencies of opening moves are distributed according to a power law with an exponent that increases linearly with the game depth, whereas the pooled distribution of all opening weights follows Zipf's law with universal exponent."
- Propose hierarchical fragmentation model that produces self-similar game trees.

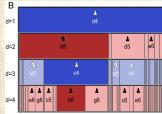

FIG. 1 (color online). (a) Schematic representation of the weighted game tree of chess based on the SCIDBASE [6] for the first three half moves. Each node indicates a state of the game. Possible game continuations are shown as solid lines together with the branching ratios r_d . Dotted lines symbolize other game continuations, which are not shown, (b) Alternative representation emphasizing the successive segmentation of the set of games, here indicated for games following a 1.d4 opening until the fourth half move d = 4. Each node σ is represented by a box of a size proportional to its frequency n_{α} . In the subsequent half move these games split into subsets (indicated vertically below) according to the possible game continuations. Highlighted in (a) and (b) is a popular opening sequence 1.d4 Nf6 2.c4 e6 (Indian defense).

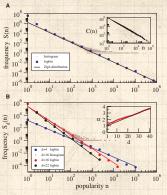

FIG. 2 (color online). (a) Histogram of weight frequencies S(n) of openings up to d = 40 in the Scid database and with logarithmic binning. A straight line fit (not shown) yields an exponent of $\alpha = 2.05$ with a goodness of fit $R^2 > 0.9992$. For comparison, the Zipf distribution Eq. (8) with $\mu=1$ is indicated as a solid line. Inset: number $C(n) = \sum_{m=n+1}^{N} S(m)$ of openings with a popularity m > n. C(n) follows a power law with exponent $\alpha = 1.04$ ($R^2 = 0.994$), (b) Number $S_d(n)$ of openings of depth d with a given popularity n for d = 16 and histograms with logarithmic binning for d = 4, d = 16, and d = 22. Solid lines are regression lines to the logarithmically binned data $(R^2 > 0.99 \text{ for } d < 35)$. Inset: slope α_d of the regression line as a function of d and the analytical estimation Eq. (6) using $N = 1.4 \times 10^6$ and $\beta = 0$ (solid line).
