Homo probabilisticus?

The set up:

☞ A parent has two children.

Simple probability question:

☞ What is the probability that both children are girls?

The next set up:

☞ A parent has two children.

☞ We know one of them is a girl.

The next probabilistic poser:

☞ What is the probability that both children are girls?

Try this one:

☞ A parent has two children.

☞ We know one of them is a girl born on a Tuesday.

Simple question #3:

☞ What is the probability that both children are girls?

Last:

☞ A parent has two children.

☞ We know one of them is a girl born on December 31.

And ...

☞ What is the probability that both children are girls?

Let's test our collective intuition:

Money
 ≡
 Belief

Two questions about wealth distribution in the United States:

1. Please estimate the percentage of all wealth owned by individuals when grouped into quintiles.
2. Please estimate what you believe each quintile should own, ideally.
3. Extremes: 100, 0, 0, 0, 0 and 20, 20, 20, 20, 20.

Wealth distribution in the United States: [13]

Fig. 2. The actual United States wealth distribution plotted against the estimated and ideal distributions across all respondents. Because of their small percentage share of total wealth, both the "4th 20%" value (0.2%) and the "Bottom 20%" value (0.1%) are not visible in the "Actual" distribution.

"Building a better America—One wealth quintile at a time"
 Norton and Ariely, 2011. [13]

Wealth distribution in the United States: [13]

Fig. 3. The actual United States wealth distribution plotted against the estimated and ideal distributions of respondents of different income levels, political affiliations, and genders. Because of their small percentage share of total wealth, both the "4th 20%" value (0.2%) and the "Bottom 20%" value (0.1%) are not visible in the "Actual" distribution.

☞ A highly watched video based on this research is

The sizes of many systems' elements appear to obey an inverse power-law size distribution:

$$P(\text{size} = x) \sim cx^{-\gamma}$$

where $0 < x_{\min} < x < x_{\max}$ and $\gamma > 1$.

☞ x_{\min} = lower cutoff, x_{\max} = upper cutoff

☞ Negative linear relationship in log-log space:

$$\log_{10} P(x) = \log_{10} c - \gamma \log_{10} x$$

☞ We use base 10 because we are good people.

Two of the many things we struggle with cognitively:

1. Probability.

- ☞ Ex. The Monty Hall Problem. ☞
- ☞ Ex. Daughter/Son born on Tuesday. ☞ (see next two slides; Wikipedia entry [here](#) ☞.)

2. Logarithmic scales.

On counting and logarithms:

- ☞ Listen to Radiolab's 2009 piece: "Numbers." ☞
- ☞ Later: Benford's Law ☞

Also to be enjoyed: the magnificence of the [Dunning-Kruger effect](#) ☞

Size distributions:

Usually, only the tail of the distribution obeys a power law:

$$P(x) \sim c x^{-\gamma} \text{ for } x \text{ large.}$$

Still use term 'power-law size distribution.'

Other terms:

- Fat-tailed distributions.
- Heavy-tailed distributions.

Beware:

Inverse power laws aren't the only ones: lognormals, Weibull distributions, ...

Size distributions:

Many systems have discrete sizes k :

- Word frequency
- Node degree in networks: # friends, # hyperlinks, etc.
- # citations for articles, court decisions, etc.

$$P(k) \sim c k^{-\gamma}$$

where $k_{\min} \leq k \leq k_{\max}$

- Obvious fail for $k = 0$.
- Again, typically a description of distribution's tail.

The statistics of surprise:

From: "Quake Moves Japan Closer to U.S. and Alters Earth's Spin" by Kenneth Chang, March 13, 2011, NYT:

"What is perhaps most surprising about the Japan earthquake is how misleading history can be. In the past 300 years, no earthquake nearly that large—nothing larger than magnitude eight—had struck in the Japan subduction zone. That, in turn, led to assumptions about how large a tsunami might strike the coast."

"It did them a giant disservice," said Dr. Stein of the geological survey. That is not the first time that the earthquake potential of a fault has been underestimated. Most geophysicists did not think the Sumatra fault could generate a magnitude 9.1 earthquake, ..."

FIG. 4. Cumulative distributions for each frequency table. The distribution parameters were computed as described in Appendix A. Data in the shaded regions were excluded from the calculations of the exponents in Table 1. Source addresses for the data are given in the text. (a) Numbers of occurrences of words in the novel Harry Potter and the Chamber of Secrets. (b) Numbers of citations in the American Online Internet archive for the day of 1 December 1997. (c) Numbers of hits on web sites by 60,000 users of the America Online Internet archive for the day of 1 December 1997. (d) Numbers of books sold in the US for the month of January 2002. (e) Numbers of telephone calls received in the US for the month of January 2002. (f) Magnitude of earthquakes in California between January 1900 and May 1992. Magnitude is proportional to the logarithm of the maximum amplitude of the earthquake, and hence the distribution above a magnitude m is proportional to the logarithm of the number of earthquakes with maximum amplitude greater than m. (g) Crater diameter in km. (h) Peak intensity of earthquakes in the US for the month of January 2002. (i) Net worth in US dollars. (j) Name frequency. (k) Population of city. (l) Population of US cities in the year 2000.

Moments

Standard deviation is a mathematical convenience:

- Variance is nice analytically ...
- Another measure of distribution width:

$$\text{Mean average deviation (MAD)} = \langle |x - \langle x \rangle| \rangle$$

- For a pure power law with $2 < \gamma < 3$:

$$\langle |x - \langle x \rangle| \rangle \text{ is finite.}$$

- But MAD is mildly unpleasant analytically ...
- We still speak of infinite 'width' if $\gamma < 3$.

Devilish power-law size distribution details:

Exhibit A:

- Given $P(x) = cx^{-\gamma}$ with $0 < x_{\min} < x < x_{\max}$, the mean is ($\gamma \neq 2$):

$$\langle x \rangle = \frac{c}{2-\gamma} (x_{\max}^{2-\gamma} - x_{\min}^{2-\gamma}).$$

- Mean 'blows up' with upper cutoff if $\gamma < 2$.
- Mean depends on lower cutoff if $\gamma > 2$.
- $\gamma < 2$: Typical sample is large.
- $\gamma > 2$: Typical sample is small.

How sample sizes grow ...

Given $P(x) \sim cx^{-\gamma}$:

- We can show that after n samples, we expect the largest sample to be¹

$$x_1 \gtrsim c' n^{1/(\gamma-1)}$$

- Sampling from a finite-variance distribution gives a much slower growth with n .
- e.g., for $P(x) = \lambda e^{-\lambda x}$, we find

$$x_1 \gtrsim \frac{1}{\lambda} \ln n.$$

[Insert assignment question](#)
[Insert assignment question](#)

¹Later, we see that the largest sample grows as n^ρ where ρ is the Zipf exponent

And in general ...

Moments:

- All moments depend only on cutoffs.
- No internal scale that dominates/matters.
- Compare to a Gaussian, exponential, etc.

For many real size distributions: $2 < \gamma < 3$

- mean is finite (depends on lower cutoff)
- $\sigma^2 = \text{variance}$ is 'infinite' (depends on upper cutoff)
- Width of distribution is 'infinite'
- If $\gamma > 3$, distribution is less terrifying and may be easily confused with other kinds of distributions.

Complementary Cumulative Distribution Function:

CCDF:

$$P_{\geq}(x) = P(x' \geq x) = 1 - P(x' < x)$$

$$= \int_{x'=x}^{\infty} P(x') dx'$$

$$\propto \int_{x'=x}^{\infty} (x')^{-\gamma} dx'$$

$$= \frac{1}{-\gamma + 1} (x')^{-\gamma+1} \Big|_{x'=x}^{\infty}$$

$$\propto x^{-(\gamma-1)}$$

Complementary Cumulative Distribution Function:

CCDF:

$$P_{\geq}(x) \propto x^{-(\gamma-1)}$$

Use when tail of P follows a power law.

Increases exponent by one.

Useful in cleaning up data.

PDF:

CCDF:

Complementary Cumulative Distribution Function:

Same story for a discrete variable: $P(k) \sim ck^{-\gamma}$.

$$P_{\geq}(k) = P(k' \geq k)$$

$$= \sum_{k'=k}^{\infty} P(k')$$

$$\propto k^{-(\gamma-1)}$$

Use integrals to approximate sums.

Zipfian rank-frequency plots

Zipf's way:

- Given a collection of entities, rank them by size, largest to smallest.
- x_r = the size of the r th ranked entity.
- $r = 1$ corresponds to the largest size.
- Example: x_1 could be the frequency of occurrence of the most common word in a text.
- Zipf's observation:

$$x_r \propto r^{-\alpha}$$

"Zipf's Law in the Popularity Distribution of Chess Openings" Blasius and Tönjes, Phys. Rev. Lett., 103, 218701, 2009. [3]

- Examined all games of varying game depth d in a set of chess databases.
- n = popularity = how many times a specific game path appears in databases.
- $S(n; d)$ = number of depth d games with popularity n .
- Show "the frequencies of opening moves are distributed according to a power law with an exponent that increases linearly with the game depth, whereas the pooled distribution of all opening weights follows Zipf's law with universal exponent."
- Propose hierarchical fragmentation model that produces self-similar game trees.

Observe:

- $NP_{\geq}(x)$ = the number of objects with size at least x where N = total number of objects.
- If an object has size x_r , then $NP_{\geq}(x_r)$ is its rank r .
- So

$$x_r \propto r^{-\alpha} = (NP_{\geq}(x_r))^{-\alpha}$$

$$\propto x_r^{-(\gamma-1)(-\alpha)} \text{ since } P_{\geq}(x) \sim x^{-(\gamma-1)}.$$

We therefore have $1 = -(\gamma-1)(-\alpha)$ or:

$$\alpha = \frac{1}{\gamma-1}$$

- A rank distribution exponent of $\alpha = 1$ corresponds to a size distribution exponent $\gamma = 2$.

FIG. 1 (color online). (a) Schematic representation of the weighted game tree of chess based on the SCIDBASE [6] for the first three half moves. Each node indicates a state of the game. Possible game continuations are shown as solid lines together with the branching ratios r_{ij} . Dotted lines symbolize other game continuations, which are not shown. (b) Alternative representation emphasizing the successive segmentation of the set of games, here indicated for games following a 1.d4 opening until the fourth half move $d = 4$. Each node σ is represented by a box of a size proportional to its frequency n_{σ} . In the subsequent half move these games split into subsets (indicated vertically below) according to the possible game continuations. Highlighted in (a) and (b) is a popular opening sequence 1.d4 Nf6 2.e4 e6 (Indian defense).

FIG. 2 (color online). (a) Histogram of weight frequencies $S(n)$ of openings up to $d = 40$ in the SCID database and with logarithmic binning. A straight line fit (not shown) yields an exponent of $\alpha = 2.05$ with a goodness of fit $R^2 > 0.9992$. For comparison, the Zipf distribution Eq. (6) with $\mu = 1$ is indicated as a solid line. Inset: number $C(n) = \sum_{m=1}^n S(m)$ of openings with a popularity $m > n$. $C(n)$ follows a power law with exponent $\alpha = 1.04$ ($R^2 = 0.994$). (b) Number $S_d(n)$ of openings of depth d with a given popularity n for $d = 16$ and histograms with logarithmic binning for $d = 4, 16$, and $d = 22$. Solid lines are regression lines to the logarithmically binned data ($R^2 > 0.99$ for $d < 35$). Inset: slope σ_d of the regression line as a function of d and the analytical estimation Eq. (6) using $N = 1.4 \times 10^6$ and $\beta = 0$ (solid line).
