"Athletics: Momentous sprint at the 2156 Olympics?" Tatem et al.,

Nature, **431**, 525–525, 2004. ^[36]

Linear extrapolation for the 100 metres:

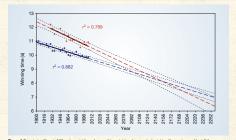

Figure 1 The winning Olympic 100-metre sprint times for men (blue points), and women (end points), with apperimposed best-fit linear regression lines gold black linear and certificiates of determination. The repression lines are entrapolated foreign blue and red lines for men and women, respectively) and 95% confidence internals (dotted black lines) based on the available points are superimposed. The projections intersect us before the 2156 Olumnics, when the Winning women's 100-metre sort inter of 8 0.075 will be faster from the mem's at 8.0085.

Tatem: 🗗 "If I'm wrong anyone is welcome to come and question me about the result after the 2156 Olympics."

- unknown equation $f(q_1, q_2, \dots, q_n) = 0$.
- & Geometric ex.: area of a square, side length ℓ : $A = \ell^2$ where $[A] = L^2$ and $[\ell] = L$.
- \mathbb{R} Rewrite as a relation of p < n independent dimensionless parameters \square where p is the number of independent dimensions (mass, length, time, luminous intensity ...):

$$F(\pi_1,\pi_2,\dots,\pi_p)=0$$

- $A/\ell^2 1 = 0$ where $\pi_1 = A/\ell^2$.
- Another example: $F = ma \Rightarrow F/ma 1 = 0$.

⁶Length is a dimension, furlongs and smoots ☑ are units

Fundamental equations cannot depend on units:

- Secometric ex.: area of a square, side length ℓ : $A=\ell^2$ where $[A]=L^2$ and $[\ell]=L$.
- Rewrite as a relation of $p \le n$ independent dimensionless parameters \square where p is the number of independent dimensions (mass, length, time, luminous intensity ...):

$$F(\pi_1,\pi_2,\dots,\pi_p)=0$$

- $\red { }$ e.g., $A/\ell^2-1=0$ where $\pi_1=A/\ell^2.$
- Another example: $F = ma \Rightarrow F/ma 1 = 0$.
- Plan: solve problems using only backs of envelopes.

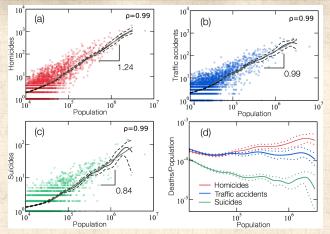

Figure 1 | Scaling relations for homicides, traffic accidents, and suicides for the year of 2009 in Brazil. The small circles show the total number of deaths y(a) homicides (red), (b) traffic accidents (blue), and (c) suicides (green) vs the population of each city. Each graph represents only one urban indicator, and the solid gray line indicate the best fit for a power-law relation, using OLS regression, between the average total number of deaths and the city size (population). To reduce the fluctuations we also performed a Nadaraya-Watson kernel regression^{17,18}. The dashed lines show the 95% confidence band for the Nadaraya-Watson kernel regression applied to the data on homicides in (a) reveals an allometric exponent $\beta = 1.24 \pm 0.01$, with a 95% confidence interval estimated by bootstrap. This is compatible with previous results obtained for U.S.² that also indicate a super-linear scaling relation with population and an exponent $\beta = 1.16$. Using the same procedure, we find $\beta = 0.99 \pm 0.02$ and 0.84 ± 0.02 for the numbers of deaths in traffic accidents (b) and suicides (c), respectively. The values of the Pearson correlation coefficients ρ associated with these scaling relations are shown in each plot. This non-linear behavior observed for homicides and suicides certainly reflects the complexity of human social relations and strongly suggests that the the topology of the social network plays an important role on the rate of these events. (d) The solid lines show the Nadaraya-Watson kernel regression rate of deaths (total number of deaths divided by the population of a city) for each urban indicator, namely, homicides (red), traffic accidents (blue), and suicides (green). The dashed lines represent the 95% confidence bands. While the rate of fatal traffic accidents remains approximately invariant, the rate of homicides systematically increases, and the rate of suicides decreases with population.

Dynamics (Brazil):

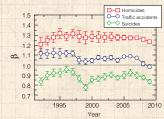

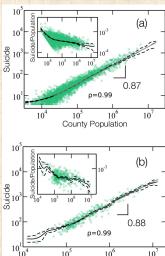

Figure 2 | Temporal evolution of allometric exponent β for homicides (red squares), deaths in traffic accidents (blue circles), and suicides (green diamonds). Time evolution of the power-law exponent β for each behavioral urban indicator in Brazil from 1992 to 2009. We can see that the non-linear behavior for homicides and suicides are robust for this 19 years period, and for the traffic accidents the exconent remain close to 1.0.

	reach, rise, run, seek, set, shake, sit, sleep, speak, stand, teach, throw, understand, walk, win, work, write			
10-4-10-3	arise, bake, bear, beat, bind, bite, blow, bow, burn, burst, carve, chew, climb, cling, creep, dare, dig, drag, flee, float,	43	2,000	
	flow, fly, fold, freeze, grind, leap, lend, lock, melt, reckon, ride, rush, shape, shine, shoot, shrink, sigh, sing, sink, slide,			
	slip, smoke, spin, spring, starve, steal, step, stretch, strike, stroke, suck, swallow, swear, sweep, swim, swing, tear,			
10-5-10-4	wake, wash, weave, weep, weigh, wind, yell, yield bark, bellow, bid, blend, braid, brew, cleave, cringe, crow,	72	700	
	dive, drip, fare, fret, glide, gnaw, grip, heave, knead, low, milk, mourn, mow, prescribe, redden, reek, row, scrape,			
	seethe, shear, shed, shove, slay, slit, smite, sow, span, spurn, sting, stink, strew, stride, swell, tread, uproot, wade,			
10-6-10-5	warp, wax, wield, wring, writhe bide, chide, delve, flay, hew, rue, shrive, slink, snip, spew,	91	300	

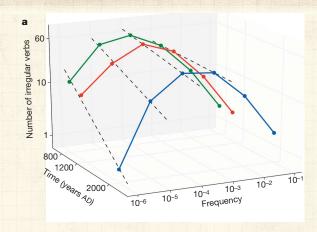

177 Old English irregular verbs were compiled for this study. These are arranged according to frequency bin, and in alphabetical order within each bin. Also shown is the percentage of verbs in each bin that have regularized. The half-life is shown in years. Verbs that have regularized are indicated in red. As we move down the list, an increasingly large fraction of the yerbs are red; the frequencydependent regularization of irregular verbs becomes immediately apparent.

Red = regularized

 \Leftrightarrow Estimates of half-life for regularization ($\propto f^{1/2}$)

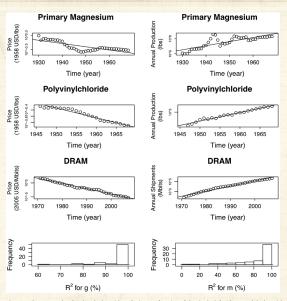

Figure 3. Three examples showing the logarithm of price as a function of time in the left column and the logarithm of production as a function of time in the right column, based on industry-wide data. We have chosen these examples to be representative: The top row contains an example with one of the worst fits, the second row an example with an intermediate goodness of fit, and the third row one of the best examples. The fourth row of the figure shows histograms of R² values for fitting g and m for the 62 datasets.

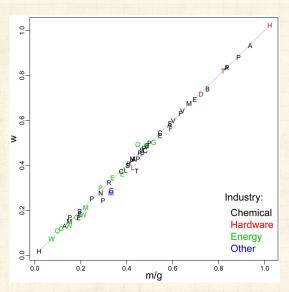

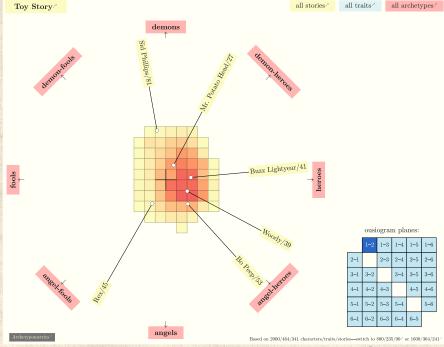

Figure 4. An illustration that the combination of exponentially increasing production and exponentially decreasing cost are equivalent to Wright's law. The value of the Wright parameter w is plotted against the prediction m/g based on the Sahal formula, where m is the exponent of cost reduction and g the exponent of the increase in cumulative production. doi:10.1371/journal.pone.0052669.g004

When the group moved to California to become part of Lucasfilm, we got close to making a computer-animated movie again in the mid-1980s – this time about a monkey with godlike powers but a missing prefrontal cortex. We had a sponsor, a story treatment, and a marketing survey. We were prepared to make a screen test: Our hot young animator John Lasseter had sketched numerous studies of the hero monkey and had the sponsor salivating over a glass-dragon protagonist.'

"But when it came time to harden the deal and run the numbers for the contracts, I discovered to my dismay that computers were still too slow: The projected production cost was too high and the computation time way too long. We had to back out of the deal. This time, we did know enough detail to correctly apply Moore's Law - and it told us that we had to wait another five years to start making the first movie. And sure enough, five years later Disney approached us to make Toy Story."

'We implement each step to see if it actually works, then gain the courage, the insight, and the engineering mastery to proceed to the next step.

Moore's Law told us that the new company we were starting, Pixar, had to bide its time—building hardware instead of making movies.'

Rhetoric of maybeness with hook to "More is different"

'That's the reason for expressing Moore's Law in orders of magnitude rather than factors of 10. The latter form is merely arithmetic, but the former implies an intellectual challenge. We use "order of magnitude" to imply a change so great that it requires new thought processes, new conceptualizations: It's not simply more, it's different.'
