## lognormals

The lognormal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

- ln x is distributed according to a normal distribution with mean  $\mu$  and variance  $\sigma$ .
- Appears in economics and biology where growth increments are distributed normally.

## Confusion between lognormals and pure power laws

Near agreement over four orders of magnitude!

- For lognormal (blue),  $\mu = 0$  and  $\sigma = 10$ .
- For power law (red),  $\gamma = 1$  and  $c = 0.03$ .

## lognormals

- Standard form reveals the mean  $\mu$  and variance  $\sigma^2$  of the underlying normal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

- For lognormals:

$$\mu_{\text{lognormal}} = e^{\mu + \frac{1}{2}\sigma^2}, \quad \text{median}_{\text{lognormal}} = e^{\mu},$$

$$\sigma_{\text{lognormal}} = (e^{\sigma^2} - 1)e^{2\mu + \sigma^2}, \quad \text{mode}_{\text{lognormal}} = e^{\mu - \sigma^2}.$$

- All moments of lognormals are **finite**.

## Confusion

What's happening:

$$\begin{aligned} \ln P(x) &= \ln \left\{ \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) \right\} \\ &= -\ln x - \ln\sqrt{2\pi\sigma} - \frac{(\ln x - \mu)^2}{2\sigma^2} \end{aligned}$$

$$= -\frac{1}{2\sigma^2}(\ln x)^2 + \left(\frac{\mu}{\sigma^2} - 1\right) \ln x - \ln\sqrt{2\pi\sigma} - \frac{\mu^2}{2\sigma^2}.$$

If the first term is relatively small,

$$\ln P(x) \sim -\left(1 - \frac{\mu}{\sigma^2}\right) \ln x + \text{const.} \Rightarrow \gamma = 1 - \frac{\mu}{\sigma^2}$$

## Alternative distributions

There are other 'heavy-tailed' distributions:

- The Log-normal distribution

$$P(x) = \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

- Weibull distributions

$$P(x)dx = \frac{k}{\lambda} \left(\frac{x}{\lambda}\right)^{\mu-1} e^{-(x/\lambda)^\mu} dx$$

CCDF = stretched exponential

- Also: Gamma distribution, Erlang distribution, and more.

## Derivation from a normal distribution

Take  $Y$  as distributed normally:

$$P(y)dy = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{(y - \mu)^2}{2\sigma^2}\right) dy$$

Set  $Y = \ln X$ :

Transform according to  $P(x)dx = P(y)dy$ :

$$\frac{dy}{dx} = 1/x \Rightarrow dy = dx/x$$

$$\Rightarrow P(x)dx = \frac{1}{x\sqrt{2\pi\sigma}} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) dx$$

## Confusion

- If  $\mu < 0$ ,  $\gamma > 1$  which is totally cool.
- If  $\mu > 0$ ,  $\gamma < 1$ , not so much.
- If  $\sigma^2 \gg 1$  and  $\mu$ ,

$$\ln P(x) \sim -\ln x + \text{const.}$$

- Expect -1 scaling to hold until  $(\ln x)^2$  term becomes significant compared to  $(\ln x)$ :  
 $-\frac{1}{2\sigma^2}(\ln x)^2 \approx 0.05 \left(\frac{\mu}{\sigma^2} - 1\right) \ln x$   
 $\Rightarrow \log_{10} x \lesssim 0.05 \times 2(\sigma^2 - \mu) \log_{10} e \approx 0.05(\sigma^2 - \mu)$
- $\Rightarrow$  If you find a -1 exponent, you may have a lognormal distribution...

## Generating lognormals:

### Random multiplicative growth:

$$x_{n+1} = rx_n$$

where  $r > 0$  is a random growth variable

(Shrinkage is allowed)

In log space, growth is by addition:

$$\ln x_{n+1} = \ln r + \ln x_n$$

$\Rightarrow \ln x_n$  is normally distributed

$\Rightarrow x_n$  is lognormally distributed

### Lognormals or power laws?

Gibrat <sup>[2]</sup> (1931) uses preceding argument to explain lognormal distribution of firm sizes ( $\gamma \approx 1$ ).

But Robert Axtell <sup>[1]</sup> (2001) shows a power law fits the data very well with  $\gamma = 2$ , not  $\gamma = 1$  (!)

Problem of data censusing (missing small firms).

$$\text{Freq} \propto (\text{size})^{-\gamma}$$

$\gamma \approx 2$

One piece in Gibrat's model seems okay empirically: Growth rate  $r$  appears to be independent of firm size. <sup>[1]</sup>.

## An explanation

Axtel cites Malcai et al.'s (1999) argument <sup>[5]</sup> for why power laws appear with exponent  $\gamma \approx 2$

The set up:  $N$  entities with size  $x_i(t)$

Generally:

$$x_i(t+1) = rx_i(t)$$

where  $r$  is drawn from some happy distribution

Same as for lognormal but one extra piece.

Each  $x_i$  cannot drop too low with respect to the other sizes:

$$x_i(t+1) = \max(rx_i(t), c(x_i))$$

## Some math later...

### Insert assignment question

$$\text{Find } P(x) \sim x^{-\gamma}$$

where  $\gamma$  is implicitly given by

$$N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[ \frac{(c/N)^{\gamma-1} - 1}{(c/N)^{\gamma-1} - (c/N)} \right]$$

$N$  = total number of firms.

$$\text{Now, if } c/N \ll 1 \text{ and } \gamma > 2 \quad N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[ \frac{-1}{-(c/N)} \right]$$

$$\text{Which gives } \gamma \sim 1 + \frac{1}{1 - c}$$

Groovy...  $c$  small  $\Rightarrow \gamma \approx 2$

## The second tweak

### Ages of firms/people/... may not be the same

Allow the number of updates for each size  $x_i$  to vary

Example:  $P(t)dt = ae^{-at}dt$  where  $t$  = age.

Back to no bottom limit: each  $x_i$  follows a lognormal

Sizes are distributed as <sup>[6]</sup>

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln x - \mu)^2}{2t}\right) dt$$

(Assume for this example that  $\sigma \sim t$  and  $\mu = \ln m$ )

Now averaging different lognormal distributions.

## Averaging lognormals

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln \frac{x}{m})^2}{2t}\right) dt$$

Insert fabulous calculation (team is spared).

Some enjoyable suffering leads to:

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda} (\ln \frac{x}{m})^2}$$

## The second tweak

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda} (\ln \frac{x}{m})^2}$$

Depends on sign of  $\ln \frac{x}{m}$ , i.e., whether  $\frac{x}{m} > 1$  or  $\frac{x}{m} < 1$ .

$$P(x) \propto \begin{cases} x^{-1+\sqrt{2\lambda}} & \text{if } \frac{x}{m} < 1 \\ x^{-1-\sqrt{2\lambda}} & \text{if } \frac{x}{m} > 1 \end{cases}$$

'Break' in scaling (not uncommon)

Double-Pareto distribution

First noticed by Montroll and Shlesinger <sup>[7, 8]</sup>

Later: Huberman and Adamic <sup>[3, 4]</sup>: Number of pages per website

## Summary of these exciting developments:

Lognormals and power laws can be awfully similar

Random Multiplicative Growth leads to lognormal distributions

Enforcing a minimum size leads to a power law tail

With no minimum size but a distribution of lifetimes, the double Pareto distribution appears

Take-home message: Be careful out there...
