## Why do things spread socially?

- Because of properties of special individuals?
- Or system level properties?
- Is the match that lights the fire important?
- Yes. But only because we are storytellers: *homo narrativus* ↗.
- We like to think things happened for reasons ...
- Reasons for success are usually ascribed to intrinsic properties (examples next).
- Teleological stories of fame are often easy to generate and believe.
- System/group dynamics harder to understand because most of our stories are built around individuals.
- Always good to examine what is said before and after the fact ...

From a 2013 [Believer Magazine](#) interview with Maurice Sendak:

BLVR: Did the success of *Where the Wild Things Are* ever feel like an albatross?

MS: It's a nice book. It's perfectly nice. I can't complain about it. I remember Herman Melville said, "When I die no one is going to mention Moby-Dick. They're all going to talk about my first book, about \*\*\*\*ing maidens in Tahiti." He was right. No mention of Moby-Dick then. Everyone wanted another Tahitian book, a beach book. But then he kept writing deeper and deeper and then came Moby-Dick and people hated it. The only ones who liked it were Mr. and Mrs. Nathaniel Hawthorne. Moby-Dick didn't get famous until 1930.

 Sendak named his dog Herman.

 The essential Colbert interview: [Pt. 1](#) and [Pt. 2](#).

 Cialdini's modes are heuristics that help up us get through life.

 Useful but can be leveraged...

Other acts of influence:

 Conspicuous Consumption (Veblen, 1912)

 Conspicuous Destruction (Potlatch)

## Some important models:

- 🧱 Tipping models—Schelling (1971) [23, 24, 25]
  - 🧱 Simulation on checker boards
  - 🧱 Idea of thresholds
  - 🧱 Polygon-themed online visualization. (Includes optional diversity-seeking proclivity.) 
- 🧱 Threshold models—Granovetter (1978) [15]
- 🧱 Herding models—Bikhchandani, Hirschleifer, Welch (1992) [2, 3]
  - 🧱 Social learning theory, Informational cascades,...

# Social contagion models

## Thresholds

- Basic idea: individuals adopt a behavior when a **certain fraction of others** have adopted
- 'Others' may be everyone in a population, an individual's close friends, any reference group.
- Response can be probabilistic or deterministic.
- Individual thresholds can vary
- Assumption: order of others' adoption does not matter... **(unrealistic)**.
- Assumption: level of influence per person is uniform **(unrealistic)**.

## Some possible origins of thresholds:

-  Inherent, evolution-devised inclination to coordinate, to conform, to imitate. <sup>[1]</sup>
-  **Lack of information:** impute the worth of a good or behavior based on degree of adoption (social proof)
-  Economics: **Network effects** or **network externalities**
  -  Externalities = Effects on others not directly involved in a transaction
  -  Examples: telephones, fax machine, TikTok, operating systems
  -  An individual's utility increases with the adoption level among peers and the population in general

# Threshold models—response functions

 Example threshold influence response functions:

**deterministic** and **stochastic**

  $\phi$  = fraction of contacts 'on' (e.g., rioting)

 Two states: S and I.

# Threshold models

Action based on perceived behavior of others:

Two states: S and I.

$\phi$  = fraction of contacts 'on' (e.g., rioting)

Discrete time update (strong assumption!)

This is a **Critical mass model**

# Threshold models

Another example of critical mass model:

# Threshold models

Example of single stable state model:

# Threshold models

Chaotic behavior possible [17, 16, 9, 18]

Period doubling arises as map amplitude  $r$  is increased.

Synchronous update assumption is crucial

## Implications for collective action theory:

1. Collective uniformity  $\nRightarrow$  individual uniformity
2. Small individual changes  $\Rightarrow$  large global changes
3. The stories/dynamics of complex systems are conceptually inaccessible for individual-centric narratives.
4. System stories live in left null space of our stories—we can't even see them.
5. But we happily impose simplistic, individual-centric stories—we can't help ourselves .

## Many years after Granovetter and Soong's work:

 "A simple model of global cascades on random networks"

D. J. Watts. Proc. Natl. Acad. Sci., 2002 [27]

 Mean field model  $\rightarrow$  network model

 Individuals now have a limited view of the world

## We'll also explore:

 "Seed size strongly affects cascades on random networks" [14]

Gleeson and Cahalane, Phys. Rev. E, 2007.

 "Direct, physically motivated derivation of the contagion condition for spreading processes on generalized random networks" [10]

Dodds, Harris, and Payne, Phys. Rev. E, 2011

 "Influentials, Networks, and Public Opinion Formation" [28]

Watts and Dodds, J. Cons. Res., 2007.

 "Threshold models of Social Influence" [29]

Watts and Dodds, The Oxford Handbook of Analytical Sociology, 2009.

# Threshold model on a network

All nodes have threshold  $\phi = 0.2$ .

# Threshold model on a network

- Interactions between individuals now represented by a network.
- Network is **sparse**.
- Individual  $i$  has  $k_i$  contacts.
- Influence on each link is **reciprocal** and of **unit weight**.
- Each individual  $i$  has a fixed threshold  $\phi_i$ .
- Individuals repeatedly poll contacts on network.
- Synchronous, discrete time updating.
- Individual  $i$  becomes active when fraction of active contacts  $\frac{a_i}{k_i} \geq \phi_i$ .
- Individuals remain active when switched (no recovery = SI model).

# Snowballing

## First study random networks:

- Start with  $N$  nodes with a degree distribution  $P_k$
- Nodes are randomly connected (carefully so)
- Aim: Figure out when activation will propagate
- Determine a **cascade condition**

## The Cascade Condition:

1. If one individual is initially activated, what is the probability that an activation will spread over a network?
2. What features of a network determine whether a cascade will occur or not?

# Example random network structure:

  $\Omega_{crit} = \Omega_{vuln} =$   
critical mass =  
global vulnerable  
component

  $\Omega_{trig} =$  triggering  
component

  $\Omega_{final} =$  potential  
extent of spread

  $\Omega =$  entire  
network

$$\Omega_{crit} \subset \Omega_{trig}; \Omega_{crit} \subset \Omega_{final}; \text{ and } \Omega_{trig}, \Omega_{final} \subset \Omega.$$

## Follow active links

-  An active link is a link connected to an activated node.
-  If an infected link leads to **at least 1 more infected link**, then **activation spreads**.
-  We need to understand which nodes can be activated when only one of their neighbors becomes active.

# The most gullible

## Vulnerables:

 We call individuals who can be activated by just one contact being active **vulnerables**

 The vulnerability condition for node  $i$ :

$$1/k_i \geq \phi_i$$

 Which means # contacts  $k_i \leq \lfloor 1/\phi_i \rfloor$

 For global cascades on random networks, must have a *global cluster of vulnerables* <sup>[27]</sup>

 **Cluster of vulnerables = critical mass**

 Network story: 1 node  $\rightarrow$  critical mass  $\rightarrow$  everyone.

# Cascade condition

Back to following a link:

 A randomly chosen link, traversed in a random direction, leads to a degree  $k$  node with probability  $\propto kP_k$ .

 Follows from there being  $k$  ways to connect to a node with degree  $k$ .

 Normalization:

$$\sum_{k=0}^{\infty} kP_k = \langle k \rangle$$

 So

$$P(\text{linked node has degree } k) = \frac{kP_k}{\langle k \rangle}$$

## Next: Vulnerability of linked node

 Linked node is **vulnerable** with probability

$$\beta_k = \int_{\phi'_*=0}^{1/k} f(\phi'_*) d\phi'_*$$

 If linked node is **vulnerable**, it produces  **$k - 1$  new** outgoing active links

 If linked node is **not vulnerable**, it produces **no** active links.

# Cascade condition

## Putting things together:

 Expected number of active edges produced by an active edge:

$$R = \left[ \sum_{k=1}^{\infty} \underbrace{(k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle}}_{\text{success}} + \underbrace{0 \cdot (1 - \beta_k) \cdot \frac{kP_k}{\langle k \rangle}}_{\text{failure}} \right]$$
$$= \sum_{k=1}^{\infty} (k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle}$$

# Cascade condition

So... for random networks with fixed degree distributions, cascades take off when:

$$\sum_{k=1}^{\infty} (k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

  $\beta_k$  = probability a degree  $k$  node is vulnerable.

  $P_k$  = probability a node has degree  $k$ .

# Cascade condition

Two special cases:

 (1) Simple disease-like spreading succeeds:  $\beta_k = \beta$

$$\beta \cdot \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

 (2) Giant component exists:  $\beta = 1$

$$1 \cdot \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

# Cascades on random networks

Cascades occur only if size of max vulnerable cluster  $> 0$ .

System may be 'robust-yet-fragile'.

'Ignorance' facilitates spreading.

# Cascade window for random networks

'Cascade window' widens as threshold  $\phi$  decreases.

Lower thresholds enable spreading.

# Cascade window for random networks

# All-to-all versus random networks

all-to-all networks

random networks

# Cascade window—summary

For our simple model of a uniform threshold:

1. Low  $\langle k \rangle$ : No cascades in poorly connected networks.  
No global clusters of any kind.
2. High  $\langle k \rangle$ : Giant component exists but not enough vulnerables.
3. Intermediate  $\langle k \rangle$ : Global cluster of vulnerables exists.  
Cascades are possible in “**Cascade window.**”

# Threshold contagion on random networks

-  **Next:** Find expected fractional size of spread.
-  Not obvious even for uniform threshold problem.
-  Difficulty is in figuring out if and when nodes that need  $\geq 2$  hits switch on.
-  Problem **beautifully solved** for infinite seed case by Gleeson and Cahalane:  
“Seed size strongly affects cascades on random networks,”  
Phys. Rev. E, 2007. <sup>[14]</sup>
-  Developed further by Gleeson in “Cascades on correlated and modular random networks,” Phys. Rev. E, 2008. <sup>[13]</sup>

# Determining expected size of spread:

- Randomly turn on a fraction  $\phi_0$  of nodes at time  $t = 0$
- Capitalize on local branching network structure of random networks (again)
- Now think about what must happen for a specific node  $i$  to become active at time  $t$ :
  - $t = 0$ :  $i$  is one of the seeds (prob =  $\phi_0$ )
  - $t = 1$ :  $i$  was not a seed but enough of  $i$ 's friends switched on at time  $t = 0$  so that  $i$ 's threshold is now exceeded.
  - $t = 2$ : enough of  $i$ 's friends and friends-of-friends switched on at time  $t = 0$  so that  $i$ 's threshold is now exceeded.
  - $t = n$ : enough nodes within  $n$  hops of  $i$  switched on at  $t = 0$  and their effects have propagated to reach  $i$ .

# Expected size of spread

● = active,  $\phi = 1/3$

$t=0$

# Expected size of spread

- Background
- Granovetter's model
- Network version
- Final size**
- Spreading success
- Groups

# Expected size of spread

## Notes:

- Calculations are possible if nodes do not become inactive (strong restriction).
- Not just for threshold model—works for a wide range of contagion processes.
- We can analytically determine the entire time evolution, not just the final size.
- We can in fact determine  $\Pr(\text{node of degree } k \text{ switching on at time } t)$ .
- Asynchronous updating can be handled too.

# Expected size of spread

Pleasantness:

- ☰ Taking off from a single seed story is about **expansion** away from a node.
- ☰ Extent of spreading story is about **contraction** at a node.

# Expected size of spread

-  **Notation:**  $\phi_{k,t} = \Pr$ (a degree  $k$  node is active at time  $t$ ).
-  **Notation:**  $B_{kj} = \Pr$ (a degree  $k$  node becomes active if  $j$  neighbors are active).
-  Our starting point:  $\phi_{k,0} = \phi_0$ .
-   $\binom{k}{j} \phi_0^j (1 - \phi_0)^{k-j} = \Pr$ ( $j$  of a degree  $k$  node's neighbors were seeded at time  $t = 0$ ).
-  Probability a degree  $k$  node was a seed at  $t = 0$  is  $\phi_0$  (as above).
-  Probability a degree  $k$  node was not a seed at  $t = 0$  is  $(1 - \phi_0)$ .
-  Combining everything, we have:

$$\phi_{k,1} = \phi_0 + (1 - \phi_0) \sum_{j=0}^k \binom{k}{j} \phi_0^j (1 - \phi_0)^{k-j} B_{kj}.$$

For general  $t$ , we need to know the probability an edge coming into a degree  $k$  node at time  $t$  is active.

**Notation:** call this probability  $\theta_t$ .

We already know  $\theta_0 = \phi_0$ .

Story analogous to  $t = 1$  case. For node  $i$ :

$$\phi_{i,t+1} = \phi_0 + (1 - \phi_0) \sum_{j=0}^{k_i} \binom{k_i}{j} \theta_t^j (1 - \theta_t)^{k_i - j} B_{k_i j}.$$

Average over all nodes to obtain expression for  $\phi_{t+1}$ :

$$\phi_{t+1} = \phi_0 + (1 - \phi_0) \sum_{k=0}^{\infty} P_k \sum_{j=0}^k \binom{k}{j} \theta_t^j (1 - \theta_t)^{k-j} B_{kj}.$$

So we need to compute  $\theta_t$ ... massive excitement...

# Expected size of spread

First connect  $\theta_0$  to  $\theta_1$ :

  $\theta_1 = \phi_0 +$

$$(1 - \phi_0) \sum_{k=1}^{\infty} \frac{k P_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_0^j (1 - \theta_0)^{k-1-j} B_{kj}$$

  $\frac{k P_k}{\langle k \rangle} = R_k = \mathbf{Pr}$  (edge connects to a degree  $k$  node).

  $\sum_{j=0}^{k-1}$  piece gives  $\mathbf{Pr}$ (degree node  $k$  activates) of its neighbors  
 $k - 1$  incoming neighbors are active.

  $\phi_0$  and  $(1 - \phi_0)$  terms account for state of node at time  $t = 0$ .

 See this all generalizes to give  $\theta_{t+1}$  in terms of  $\theta_t$ ...

# Expected size of spread

Two pieces: edges first, and then nodes

$$1. \theta_{t+1} = \underbrace{\phi_0}_{\text{exogenous}}$$

$$+(1 - \phi_0) \underbrace{\sum_{k=1}^{\infty} \frac{k P_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_t^j (1 - \theta_t)^{k-1-j} B_{kj}}_{\text{social effects}}$$

with  $\theta_0 = \phi_0$ .

$$2. \phi_{t+1} =$$

$$\underbrace{\phi_0}_{\text{exogenous}} + (1 - \phi_0) \underbrace{\sum_{k=0}^{\infty} P_k \sum_{j=0}^k \binom{k}{j} \theta_t^j (1 - \theta_t)^{k-j} B_{kj}}_{\text{social effects}}.$$

# Expected size of spread

Iterative map for  $\theta_t$  is key:

$$\theta_{t+1} = \underbrace{\phi_0}_{\text{exogenous}}$$

$$+(1 - \phi_0) \underbrace{\sum_{k=1}^{\infty} \frac{k P_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_t^j (1 - \theta_t)^{k-1-j} B_{kj}}_{\text{social effects}}$$

$$= G(\theta_t; \phi_0)$$

## Expected size of spread:

- Retrieve cascade condition for spreading from a single seed in limit  $\phi_0 \rightarrow 0$ .
- Depends on map  $\theta_{t+1} = G(\theta_t; \phi_0)$ .
- First: if self-starters are present, some activation is assured:

$$G(0; \phi_0) = \sum_{k=1}^{\infty} \frac{kP_k}{\langle k \rangle} \bullet B_{k0} > 0.$$

meaning  $B_{k0} > 0$  for at least one value of  $k \geq 1$ .

- If  $\theta = 0$  is a fixed point of  $G$  (i.e.,  $G(0; \phi_0) = 0$ ) then spreading occurs if

$$G'(0; \phi_0) = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \bullet (k-1) \bullet B_{k1} > 1.$$

## Expected size of spread:

In words:

- ☰ If  $G(0; \phi_0) > 0$ , spreading must occur because some nodes turn on for free.
- ☰ If  $G$  has an **unstable fixed point** at  $\theta = 0$ , then cascades are also always possible.

Non-vanishing seed case:

- ☰ Cascade condition is more complicated for  $\phi_0 > 0$ .
- ☰ If  $G$  has a **stable fixed point** at  $\theta = 0$ , and an **unstable fixed point** for some  $0 < \theta_* < 1$ , then for  $\theta_0 > \theta_*$ , spreading takes off.
- ☰ Tricky point:  $G$  depends on  $\phi_0$ , so as we change  $\phi_0$ , we also change  $G$ .
- ☰ A version of a critical mass model again.

# General fixed point story:

 Given  $\theta_0 (= \phi_0)$ ,  $\theta_\infty$  will be the nearest stable fixed point, either above or below.

 n.b., adjacent fixed points must have opposite stability types.

 **Important:** Actual form of  $G$  depends on  $\phi_0$ .

 So choice of  $\phi_0$  dictates both  $G$  and starting point—can't start anywhere for a given  $G$ .

# Early adopters—degree distributions

$P_{k,t}$  versus  $k$

## “Influentials, Networks, and Public Opinion Formation”

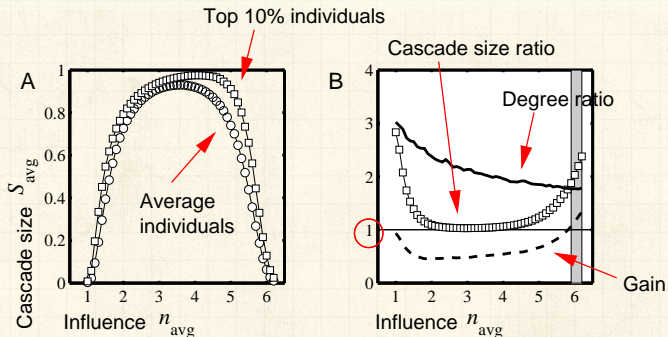

Watts and Dodds,

J. Consum. Res., **34**, 441–458, 2007. [28]

-  Exploration of threshold model of social contagion on various networks.
-  “Influentials” are limited in power.
-  Connected groups of weakly influential-vulnerable” individuals are key.
-  Average individuals can have more power than well connected ones.

# The multiplier effect:

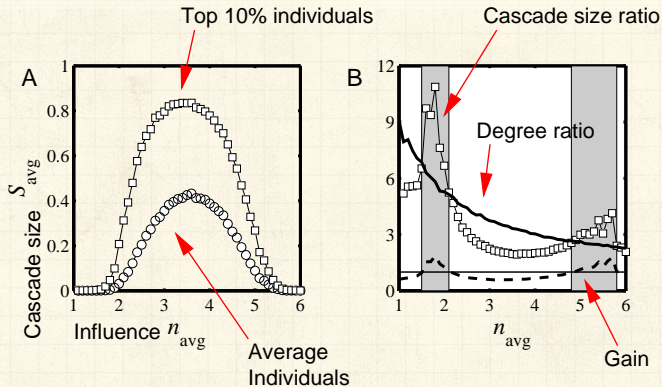

Fairly uniform levels of individual influence.

Multiplier effect is mostly below 1.

# The multiplier effect:

Skewed influence distribution example.

# Special subnetworks can act as triggers

  $\phi = 1/3$  for all nodes

# The power of groups...

**TEAMWORK**

A FEW HARMLESS FLAKES WORKING TOGETHER CAN  
UNLEASH AN AVALANCHE OF DESTRUCTION.

[www.despair.com](http://www.despair.com)

“A few harmless flakes  
working together can  
unleash an avalanche of  
destruction.”

## “Threshold Models of Social Influence”

Watts and Dodds,

The Oxford Handbook of Analytical Sociology, **34**,  
475–497, 2009. <sup>[29]</sup>

-  Assumption of sparse interactions is good
-  Degree distribution is (generally) key to a network's function
-  Still, random networks don't represent all networks
-  Major element missing: **group structure**

 Connect nodes with probability  $\propto e^{-\alpha d}$

where

$\alpha$  = homophily parameter

and

$d$  = distance between nodes (height of lowest common ancestor)

  $\tau_1$  = intergroup probability of friend-of-friend connection

  $\tau_2$  = intragroup probability of friend-of-friend connection

# Cascade windows for group-based networks

# Multiplier effect for group-based networks:

Multiplier almost always below 1.

# Assortativity in group-based networks

The most connected nodes aren't always the most 'influential.'

**Degree assortativity** is the reason.

# Social contagion

“Without followers, evil cannot spread.” –Leonard Nimoy

## Summary

- 🧱 **‘Influential vulnerables’** are key to spread.
- 🧱 Early adopters are mostly vulnerables.
- 🧱 Vulnerable nodes important but not necessary.
- 🧱 Groups may greatly facilitate spread.
- 🧱 Seems that cascade condition is a global one.
- 🧱 Most extreme/unexpected cascades occur in highly connected networks
- 🧱 ‘Influentials’ are posterior constructs.
- 🧱 Many potential influentials exist.

# Social contagion

## Implications

- Focus on **the influential vulnerables**.
- Create entities that can be transmitted successfully through many individuals rather than broadcast from one 'influential.'
- Only **simple ideas** can spread by word-of-mouth.  
(Idea of opinion leaders spreads well...)
- Want enough individuals who will adopt and display.
- Displaying can be **passive** = free (fashion),  
or **active** = harder to achieve (political messages; even so:  
buttons and hats).
- Entities can be novel or designed to combine with others, e.g.  
block another one.
