Outline

Random walks on networks

Random walks on networks—basics:

- lmagine a single random walker moving around on a network.
- At t = 0, start walker at node j and take time to be discrete.
- 🚯 Q: What's the long term probability distribution for where the walker will be?
- Befine $p_i(t)$ as the probability that at time step t, our walker is at node *i*.
- We want to characterize the evolution of $\vec{p}(t)$.
- Sirst task: connect $\vec{p}(t+1)$ to $\vec{p}(t)$.
- Let's call our walker Barry.
- 🚯 Unfortunately for Barry, he lives on a high dimensional graph and is far from home.
- Norse still: Barry is texting.

Where is Barry?

- lacktrian consider simple undirected, ergodic (strongly connected) networks. Random walks on As usual, represent network by adjacency matrix
 - A where
 - $a_{ij} = 1$ if *i* has an edge leading to *j*, $a_{ii} = 0$ otherwise.
 - Barry is at node j at time t with probability $p_i(t)$.
 - ln the next time step, he randomly lurches toward one of j's neighbors.
 - \bigotimes Barry arrives at node *i* from node *j* with probability $\frac{1}{k_i}$ if an edge connects *j* to *i*.
 - Equation-wise:

$$p_i(t+1) = \sum_{j=1}^n \frac{1}{k_j} a_{ji} p_j(t).$$

where k_i is j's degree. Note: $k_i = \sum_{i=1}^n a_{ij}$.

- Inebriation and diffusion:
- Excellent observation: The same equation applies for stuff moving around a network, such that at each time step all material at node i is sent to its neighbors.
- $x_i(t)$ = amount of stuff at node *i* at time *t*.

$$x_i(t+1) = \sum_{j=1}^n \frac{1}{k_j} a_{ji} x_j(t)$$

 $p_i(t+1) = \sum_{j=1}^n a_{ji} \frac{1}{k_i} p_j(t)$ is more usefully viewed

 $\vec{p}(t+1) = A^{\mathsf{T}} K^{-1} \vec{p}(t)$

where $[K_{ij}] = [\delta_{ij}k_i]$ has node degrees on the

So... we need to find the dominant eigenvalue of

The corresponding eigenvector will be the limiting probability distribution (or invariant measure).

Extra concerns: multiplicity of eigenvalue = 1, and

main diagonal and zeros everywhere else.

Expect this eigenvalue will be 1 (doesn't make)

sense for total probability to change).

network connectedness.

Random walking is equivalent to diffusion C.

Linear algebra-based excitement:

Random walks on

- 🙈 By inspection, we see that
 - $\vec{p}(\infty) = \frac{1}{\sum_{i=1}^{n} k_i} \vec{k}$
 - satisfies $\vec{p}(\infty) = A^{\mathsf{T}} K^{-1} \vec{p}(\infty)$ with eigenvalue 1.
- \bigotimes We will find Barry at node *i* with probability proportional to its degree k_i .
- 🗞 Beautiful implication: probability of finding Barry travelling along any edge is uniform.
- Diffusion in real space smooths things out.
- On networks, uniformity occurs on edges.
- So in fact, diffusion in real space is about the edges too but we just don't see that.

Random walks or

networks

- Solution $A^{\mathsf{T}}K^{-1}$ is similar to a real symmetric matrix if $A = A^{\mathsf{T}}$.
- Solution Consider the transformation $M = K^{-1/2}$:

$K^{-1/2} A^{\mathsf{T}} K^{-1} K^{1/2} = K^{-1/2} A^{\mathsf{T}} K^{-1/2}.$

Since $A^{\mathsf{T}} = A$, we have

 $(K^{-1/2}AK^{-1/2})^{\mathsf{T}} = K^{-1/2}AK^{-1/2}.$

- \mathbb{R} Upshot: $A^{\mathsf{T}}K^{-1} = AK^{-1}$ has real eigenvalues and a complete set of orthogonal eigenvectors.
- Can also show that maximum eigenvalue magnitude is indeed 1.
