Random bipartite networks:

We'll follow this rather well cited **☑** paper:

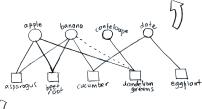

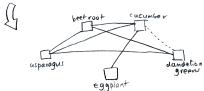

"Random graphs with arbitrary degree distributions and their applications" Newman, Strogatz, and Watts, Phys. Rev. E, **64**, 026118, 2001. [7]

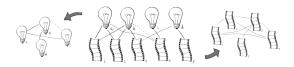

Example of a bipartite affiliation network and the induced networks:

- & Center: A small story-trope bipartite graph. [2]
- Induced trope network and the induced story network are on the left and right.
- The dashed edge in the bipartite affiliation network indicates an edge added to the system, resulting in the dashed edges being added to the two induced networks.

Basic story:

- An example of two inter-affiliated types:
 - ♀ = tropes ☑.
- Stories contain tropes, tropes are in stories.
- & Consider a story-trope system with N_{\blacksquare} = # stories and N_{Ω} = # tropes.
- $\Re m_{\square \square \square}$ = number of edges between \square and \square .
- Let's have some underlying distributions for numbers of affiliations: $P_k^{(\blacksquare)}$ (a story has k tropes) and $P_h^{(\mathbb{Q})}$ (a trope is in k stories).
- \mathbb{A} Average number of affiliations: $\langle k \rangle_{\mathbb{H}}$ and $\langle k \rangle_{\mathbb{Q}}$.
 - $\langle k \rangle_{\square}$ = average number of tropes per story.
 - $\langle k \rangle_{\mathbb{Q}}$ = average number of stories containing a

Generating Function Madness

Yes, we're doing it:

$$F_{P^{(0)}}(x) = \sum_{k=0}^{\infty} P_k^{(0)} x^k$$

$$\mbox{\&} \ F_{R^{(\mathbf{\hat{q}})}}(x) = \sum_{k=0}^{\infty} R_k^{(\mathbf{\hat{q}})} x^k = \frac{F_{P^{(\mathbf{\hat{q}})}}'(x)}{F_{P^{(\mathbf{\hat{q}})}}'(1)}$$

The usual goodness:

$$\&$$
 Means: $F'_{P^{(\blacksquare)}}(1) = \langle k \rangle_{\blacksquare}$ and $F'_{P^{(\triangledown)}}(1) = \langle k \rangle_{\lozenge}$.

We strap these in as well: @pocsvox Random Bipartite

$$F_{R_{\mathrm{ind}}^{(\mathbb{N}-\mathbb{H})}}(x) = \sum_{k=0}^{\infty} R_{\mathrm{ind},k}^{(\mathbb{N}-\mathbb{H})} x^k$$

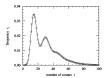

$$\begin{array}{c} F_{R_{\mathrm{ind}}}(x) = \sum_{k=0}^{\infty} R_{\mathrm{ind},k}^{\mathrm{ind},k} x \\ \\ & \Longrightarrow F_{R_{\mathrm{ind}}}(x) = \sum_{k=0}^{\infty} R_{\mathrm{ind},k}^{(\blacksquare - \P)} x^{k} \end{array}$$

So how do all these things connect?

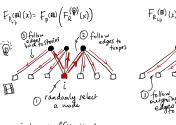

- We're again performing sums of a randomly chosen number of randomly chosen numbers.
- We use one of our favorite sneaky tricks:

$$W = \sum_{i=1}^{U} V^{(i)} \rightleftharpoons F_W(x) = F_U(F_V(x)).$$

Induced distributions are not straightforward:

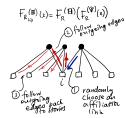

- $\mbox{\&}$ View this as $P_{\mathrm{ind},k}^{(\blacksquare)}$ (the probability a story shares tropes with k other stories). [7]
- Result of purely random wiring with Poisson distributions for affiliation numbers.
- $\begin{array}{ll} \& & \text{Parameters: } N_{\blacksquare} = 10^4 \text{, } N_{\lozenge} = 10^5 \text{,} \\ \langle k \rangle_{\blacksquare} = 1.5 \text{, and } \langle k \rangle_{\lozenge} = 15. \end{array}$

i has degree 6 in induced story network

* seems i has 3 outgoing edges * fine for distributions

Induced distribution for stories:

Induced distribution for tropes:

 \mathbb{R} Randomly choose a \mathbb{H} , find its tropes (U), and then find how many other stories each of those tropes are part of (V):

$$F_{P_{\mathrm{ind}}^{(\blacksquare)}}(x) = F_{P_{\mathrm{ind}}^{(\blacksquare)}}(x) = F_{P^{(\blacksquare)}}\left(F_{R^{(\P)}}(x)\right)$$

Find the
at the end of a randomly chosen affiliation edge leaving a trope, find its number of other tropes (*U*), and then find how many other stories each of those tropes are part of (*V*):

$$F_{R_{\mathrm{ind}}^{(\mathrm{Q}-\mathrm{lin})}}(x) = F_{R^{(\mathrm{lin})}}\left(F_{R^{(\mathrm{Q})}}(x)\right)$$

•9 q (→ 29 of 43

PoCS Random Bipartite

Introduction

Basic story References

of those stories (V):

Randomly choose a \mathfrak{P} , find the stories its part of

(U), and then find how many other tropes are part

 $F_{P^{(\mathbf{\tilde{q}})}}(x) = F_{P^{(\mathbf{\tilde{q}})}}(x) = F_{P^{(\mathbf{\tilde{q}})}}\left(F_{R^{(\mathbf{\tilde{q}})}}(x)\right)$

 \clubsuit Find the \heartsuit at the end of a randomly chosen affiliation edge leaving a story, find the number of other stories that use it (U), and then find how many other tropes are in those stories (V):

$$F_{R^{(\square - \mathbb{Q})}}(x) = F_{R^{(\mathbb{Q})}}\left(F_{R^{(\square)}}(x)\right)$$

III |

III |

Let's do some good:

Average number of stories connected to a story through trope-space:

$$\langle k \rangle_{\boxminus, \mathrm{ind}} = F'_{P_{\mathrm{ind}}^{(\boxminus)}}(1)$$

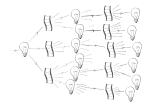

$$\begin{split} &\operatorname{So:} \langle k \rangle_{\boxplus,\operatorname{ind}} = \left. \frac{\operatorname{d}}{\operatorname{d} x} F_{P^{(\boxtimes)}} \left(F_{R^{(\lozenge)}}(x) \right) \right|_{x=1} \\ &= F'_{R^{(\lozenge)}}(1) F'_{P^{(\boxtimes)}} \left(F_{R^{(\lozenge)}}(1) \right) = F'_{R^{(\lozenge)}}(1) F'_{P^{(\boxtimes)}}(1) \end{split}$$

Similarly, the average number of tropes connected to a random trope through stories:

$$\langle k \rangle_{\mathbb{Q},\mathrm{ind}} = F'_{R^{(\mathbb{H})}}(1)F'_{P^{(\mathbb{Q})}}(1)$$

In terms of the underlying distributions, we have: $\langle k \rangle_{\boxminus,\mathsf{ind}} = \frac{\langle k(k-1) \rangle_{\lozenge}}{\langle k \rangle_{\lozenge}} \langle k \rangle_{\boxminus} \text{ and } \langle k \rangle_{\lozenge,\mathsf{ind}} = \frac{\langle k(k-1) \rangle_{\boxminus}}{\langle k \rangle_{\boxminus}} \langle k \rangle_{\lozenge}$

Spreading through bipartite networks:

- Niew as bouncing back and forth between the two connected populations. [2]
- Actual spread may be within only one population (ideas between between people) or through both (failures in physical and communication networks).
- A The gain ratio for simple contagion on a bipartite random network = product of two gain ratios.

Introduction

Basic story

 $\langle k \rangle_{R,\boxminus,\mathrm{ind}} = \frac{\langle k(k-1) \rangle_{\boxminus}}{\langle k \rangle_{\boxminus}} \frac{\langle k(k-1) \rangle_{\lozenge}}{\langle k \rangle_{\lozenge}}$

We have a giant component in both induced networks

$$\langle k \rangle_{R, \boxminus, \mathrm{ind}} \equiv \langle k \rangle_{R, \heartsuit, \mathrm{ind}} > 1$$

- See this as the product of two gain ratios. #excellent #physics
- We can mess with this condition to make it mathematically pleasant and pleasantly inscrutable:

$$\sum_{k=0}^{\infty}\sum_{k'=0}^{\infty}kk'(kk'-k-k')P_k^{(\blacksquare)}P_{k'}^{(\P)}=0.$$

Random Bipartite

Basic story

.... |S

PoCS

@pocsvox

少 Q (~ 31 of 43

 \mathfrak{S} Set $P_{h}^{(\blacksquare)} = \delta_{h3}$ and leave $P_{h}^{(\lozenge)}$ arbitrary.

 $F_{P^{(\mathbb{Q})}}(x) = F_{P^{(\mathbb{Q})}}\left(F_{R^{(\mathbb{H})}}(x)\right)$ we have $F_{P^{(\mathbf{Q})}_{-}}(x)=\left[F_{R^{(\mathbf{Q})}}(x)\right]^{3} \text{ and } F_{P^{(\mathbf{Q})}_{-}}(x)=F_{P^{(\mathbf{Q})}_{-}}\left(x^{2}\right).$

Even more specific: If each trope is found in exactly two stories then $F_{P(\overline{Y})} = x^2$ and $F_{R(\overline{Y})} = x$

A Yes for giant components \square : $\langle k \rangle_{R, \square, \text{ind}} \equiv \langle k \rangle_{R, \square, \text{ind}} = 2 \cdot 1 = 2 > 1.$

W | |

◆) q (→ 32 of 43

Unstoppable spreading: is this thing connected?

- Always about the edges: when following a random edge toward a E, what's the expected number of new edges leading to other stories via tropes?
- $\mbox{\&}$ We want to determine $\langle k \rangle_{R, \boxminus, \rm ind} = F'_{R_{\rm cool}^{(\rm V-} \boxminus)}(1)$ (and $F_{{}_{B}^{(\square - \mathbb{Q})}}'(1)$ for the trope side of things).
- We compute with joy:

$$\begin{split} \langle k \rangle_{R, \boxminus, \mathrm{ind}} &= \left. \frac{\mathrm{d}}{\mathrm{d}x} F_{R_{\mathrm{ind},k}^{(\mathbb{Q}-\mathbb{H})}}(x) \right|_{x=1} = \left. \frac{\mathrm{d}}{\mathrm{d}x} F_{R^{(\mathbb{H})}} \left(F_{R^{(\mathbb{Q})}}(x) \right) \right|_{x=1} \\ &= F_{R^{(\mathbb{Q})}}'(1) F_{R^{(\mathbb{H})}}' \left(F_{R^{(\mathbb{Q})}}(1) \right) = F_{R^{(\mathbb{Q})}}'(1) F_{R^{(\mathbb{H})}}'(1) = \frac{F_{P^{(\mathbb{Q})}}''(1)}{F_{P^{(\mathbb{Q})}}'(1)} \frac{F_{P^{(\mathbb{H})}}''(1)}{F_{P^{(\mathbb{H})}}'(1)} \end{split}$$

- Note symmetry.
- \$happiness++;

In terms of the underlying distributions:

$$\langle k \rangle_{R, \boxminus, \mathrm{ind}} = \frac{\langle k(k-1) \rangle_{\boxminus}}{\langle k \rangle_{\boxminus}} \frac{\langle k(k-1) \rangle_{\lozenge}}{\langle k \rangle_{\lozenge}}$$

$$\langle k \rangle_{R, \boxminus, \text{ind}} \equiv \langle k \rangle_{R, \heartsuit, \text{ind}} > 1$$

$$\sum_{k=0}^{\infty}\sum_{k'=0}^{\infty}kk'(kk'-k-k')P_k^{(\blacksquare)}P_{k'}^{(\P)}=0.$$

Simple example for finding the degree distributions for the two induced networks in a random bipartite affiliation structure:

$$\begin{split} & & \text{Using } F_{P_{\text{ind}}^{(\textbf{Q})}}(x) = F_{P^{(\textbf{Q})}}\left(F_{R^{(\textbf{Q})}}(x)\right) \text{ and } \\ & F_{P_{\text{ind}}^{(\textbf{Q})}}(x) = F_{P^{(\textbf{Q})}}\left(F_{R^{(\textbf{Q})}}(x)\right) \text{ we have } \\ & F_{P_{\text{ind}}^{(\textbf{Q})}}(x) = \left[F_{R^{(\textbf{Q})}}(x)\right]^3 \text{ and } F_{P_{\text{ind}}^{(\textbf{Q})}}(x) = F_{P^{(\textbf{Q})}}\left(x^2\right) \end{split}$$

- giving $F_{P_{\text{lad}}^{(\!\!|\!\!|\!\!|\!\!|}}(x)=x^3$ and $F_{P_{\text{lad}}^{(\!\!|\!\!|\!\!|\!\!|}}(x)=x^4.$

Boards and Directors: [7]

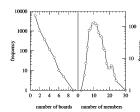

FIG. 8. Frequency distributions for the boards of directors of the Fortune 1000. Left panel: the numbers of boards on which each director sits. Right panel: the numbers of directors on each board

- & Exponentialish distribution for number of boards each director sits on.
- Boards typically have 5 to 15 directors.
- Plan: Take these distributions, presume random bipartite structure and generate co-director network and board interlock network.

Boards and Directors: [7]

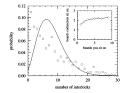

FIG. 10. The distribution of the number of other boards with which each board of directors is "interlocked" in the Fortune 1000 data. An interlock between two boards means that they share one or more common members. The points are the empirical data, the solid line is the theoretical prediction. Inset: the number of boards or which one's codirectors sit, as a function of the number of board

- Wins less bananas for the board interlock network.
- Assortativity is the reason: Directors who sit on many boards tend to sit on the same boards.
- Note: The term assortativity was not used in this 2001 paper.

◆9 q (~ 39 of 43

To come:

- Distributions of component size.
- Simpler computation for the giant component condition.
- Contagion.
- Testing real bipartite structures for departure from randomness.

Nutshell:

- Random bipartite networks model many real systems well.
- & Crucial improvement over simple random networks.
- & We can find the induced distributions and determine connectivity/contagion condition.
