The SCALES

A power law relates two variables x and y as follows:

$$y = cx^{\alpha}$$

- α is the scaling exponent (or just exponent)
- α can be any number in principle but we will find various restrictions.

Isometry versus Allometry:

- & Iso-metry = 'same measure'
- Allo-metry = 'other measure'

We use allometric scaling to refer to both:

- 1. Nonlinear scaling of a dependent variable on an independent one (e.g., $y \propto x^{1/3}$)
- 2. The relative scaling of correlated measures (e.g., white and gray matter).

An interesting, earlier treatise on scaling:

The many scales of life:

The biggest living things (left). All the organisms are drawn to the same scale. 1, The largest flying bird (albatross); 2, the largest known animal (the blue whale), 3, the largest extinct land mammal (Baluchitherium) with a human figure shown for scale: 4, the tallest living land animal (giraffe); 5, Tvrannosaurus: 6. Diplodocus: 7. one of the largest flying reptiles (Pteranodon); 8, the largest extinct snake: 9, the length of the largest tapeworm found in man: 10. the largest living reptile (West African crocodile): 11, the largest extinct lizard: 12, the largest extinct bird (Aepyornis); 13, the largest jellyfish (Cyanea); 14, the largest living lizard (Komodo dragon); 15, sheep; 16, the largest bivalve mollusc (Tridacna); 17; the largest fish (whale shark); 18, horse; 19, the largest crustacean (Japanese spider crab); 20, the largest sea scorpion (Eurypterid); 21, large tarpon; 22, the largest lobster: 23, the largest mollusc (deep-water squid, Architeuthis); 24, ostrich; 25, the lower 105 feet of the largest organism (giant seguoia), with a 100-foot larch superposed.

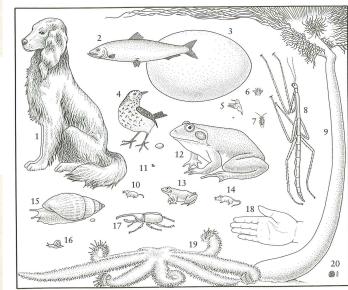

p. 2, McMahon and Bonner ^[26]

The many scales of life:

Medium-sized creatures (above), 1, Dog; 2, common herring; 3, the largest egg (Aepyornis); 4, song thrush with egg; 5, the smallest bird (hummingbird) with egg; 6, queen bee; 7, common cockroach; 8, the largest stick insect; 9, the largest polyp (Branchiocerianthus): 10, the smallest mammal (flying shrew); 11, the smallest vertebrate (a tropical frog); 12, the largest frog (goliath frog); 13, common grass frog; 14, house mouse: 15, the largest land snail (Achatina) with egg; 16, common snail; 17, the largest beetle (goliath beetle); 18, human hand; 19, the largest starfish (Luidia); 20, the largest free-moving protozoan (an extinct nummulite).

p. 3, McMahon and Bonner [26]
More on the Elephant Bird here .

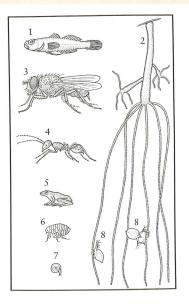

The many scales of life:

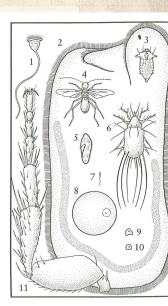

Small, "naked-eye" creatures (lower left).

1, One of the smallest fishes (Trimmator narus); 2, common brown hydra, expanded; 3, housefly; 4, medium-sized and 5, the smallest vertebrate (a tropical frog, the same as the one numbered 11 in the figure above); 6, flea (Xenopsylla cheopis); 7, the smallest land snail; 8, common water flea (Daphnia).

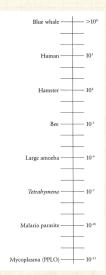

The smallest "naked-eye" creatures and some large microscopic aimais and cells (below right). 1, Vorticella, a ciliate; 2, the largest ciliate protocoan (Bursaria); 3, the smallest many-celled animal (a rotifer); 4, smallest flying insect (Eaphyls); 5, another ciliate (Paramecium); 6, cheese mite; 7, human spern, 8, human own; 9, smallest flying of the flower to the left).

p. 3, McMahon and Bonner ^[26]

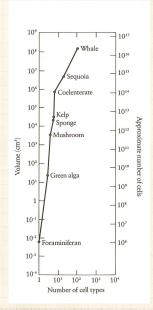

Size range (in grams) and cell differentiation:

 10^{-13} to 10^8 g, p. 3, McMahon and Bonner [26]

- System involves n related quantities with some unknown equation $f(q_1,q_2,\dots,q_n)=0.$
- Geometric ex.: area of a square, side length ℓ : $A=\ell^2$ where $[A]=L^2$ and $[\ell]=L$.
- Rewrite as a relation of $p \le n$ independent dimensionless parameters \square where p is the number of independent dimensions (mass, length, time, luminous intensity ...):

$$F(\pi_1,\pi_2,\dots,\pi_p)=0$$

- \clubsuit Another example: $F = ma \Rightarrow F/ma 1 = 0$.
- Plan: solve problems using only backs of envelopes.

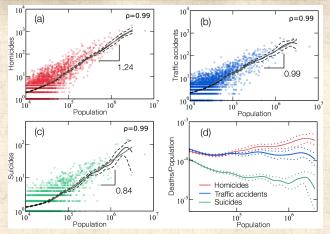

Figure 1 | Scaling relations for homicides, traffic accidents, and suicides for the year of 2009 in Brazil. The small circles show the total number of deaths y(a) homicides (red), (b) traffic accidents (blue), and (c) suicides (green) vs the population of each city. Each graph represents only one urban indicator, and the solid gray line indicate the best fit for a power-law relation, using OLS regression, between the average total number of deaths and the city size (population). To reduce the fluctuations we also performed a Nadaraya-Watson kernel regression^{17,18}. The dashed lines show the 95% confidence band for the Nadaraya-Watson kernel regression applied to the data on homicides in (a) reveals an allometric exponent $\beta = 1.24 \pm 0.01$, with a 95% confidence interval estimated by bootstrap. This is compatible with previous results obtained for U.S.² that also indicate a super-linear scaling relation with population and an exponent $\beta = 1.16$. Using the same procedure, we find $\beta = 0.99 \pm 0.02$ and 0.84 ± 0.02 for the numbers of deaths in traffic accidents (b) and suicides (c), respectively. The values of the Pearson correlation coefficients ρ associated with these scaling relations are shown in each plot. This non-linear behavior observed for homicides and suicides certainly reflects the complexity of human social relations and strongly suggests that the the topology of the social network plays an important role on the rate of these events. (d) The solid lines show the Nadaraya-Watson kernel regression rate of deaths (total number of deaths divided by the population of a city) for each urban indicator, namely, homicides (red), traffic accidents (blue), and suicides (green). The dashed lines represent the 95% confidence bands. While the rate of fatal traffic accidents remains approximately invariant, the rate of homicides systematically increases, and the rate of suicides decreases with population.

Dynamics (Brazil):

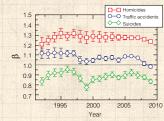

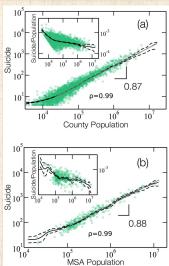

Figure 2 | Temporal evolution of allometric exponent β for homicides (red squares), deaths in traffic accidents (blue circles), and suicides (green diamonds). Time evolution of the power-law exponent β for each behavioral urban indicator in Brazil from 1992 to 2009. We can see that the non-linear behavior for homicides and suicides are robust for this 19 years period, and for the traffic accidents the exponent remain close to 1.0.

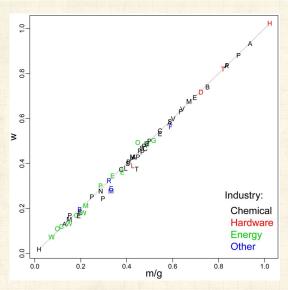

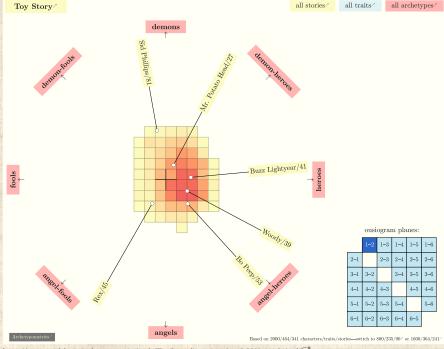

Figure 4. An illustration that the combination of exponentially increasing production and exponentially decreasing cost are equivalent to Wright's law. The value of the Wright parameter w is plotted against the prediction m/g based on the Sahal formula, where m is the exponent of cost reduction and g the exponent of the increase in cumulative production. doi:10.1371/journal.pone.0052669.g004

'When the group moved to California to become part of Lucasfilm, we got close to making a computer-animated movie again in the mid-1980s - this time about a monkey with godlike powers but a missing prefrontal cortex. We had a sponsor, a story treatment, and a marketing survey. We were prepared to make a screen test: Our hot young animator John Lasseter had sketched numerous studies of the hero monkey and had the sponsor salivating over a glass-dragon protagonist.'

"But when it came time to harden the deal and run the numbers for the contracts, I discovered to my dismay that computers were still too slow: The projected production cost was too high and the computation time way too long. We had to back out of the deal. This time, we did know enough detail to correctly apply Moore's Law – and it told us that we had to wait another five years to start making the first movie. And sure enough, five years later Disney approached us to make Toy Story."

Rhetoric of maybeness with hook to "More is different"

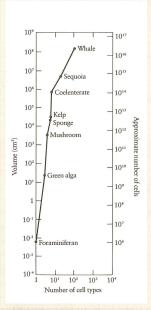

'That's the reason for expressing Moore's Law in orders of magnitude rather than factors of 10. The latter form is merely arithmetic, but the former implies an intellectual challenge. We use "order of magnitude" to imply a change so great that it requires new thought processes, new conceptualizations: It's not simply more, it's different.'
