■ uninfected
 ■ infected

- 🧩 **General spreading mechanism:** State of node i depends on history of i and i 's neighbors' states.
- 🧩 **Doses** of entity may be stochastic and history-dependent.
- 🧩 May have **multiple, interacting entities** spreading at once.

Global spreading condition

🧩 Our global spreading condition is then:

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1} > 1.$$

🧩 **Case 1:** If $B_{k1} = 1$ then

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) = \frac{\langle k(k-1) \rangle}{\langle k \rangle} > 1.$$

🧩 **Good:** This is just our giant component condition again.

Spreading on Random Networks

- 🧩 For random networks, we know local structure is pure branching.
- 🧩 Successful spreading is \therefore contingent on **single edges** infecting nodes.

- 🧩 Focus on **binary** case with edges and nodes either infected or not.
- 🧩 **First big question:** for a given network and contagion process, can global spreading from a single seed occur?

Global spreading condition

🧩 **Case 2:** If $B_{k1} = \beta < 1$ then

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot \beta > 1.$$

- 🧩 A fraction $(1-\beta)$ of edges do not transmit infection.
- 🧩 Analogous phase transition to giant component case but **critical value** of $\langle k \rangle$ is increased.
- 🧩 Aka bond percolation \square .
- 🧩 Resulting degree distribution \tilde{P}_k :

$$\tilde{P}_k = \beta^k \sum_{i=k}^{\infty} \binom{i}{k} (1-\beta)^{i-k} P_i.$$

- Insert assignment question \square
- 🧩 We can show $F_{\tilde{P}}(x) = F_P(\beta x + 1 - \beta)$.

Contagion models

Some large questions concerning network contagion:

1. For a given **spreading mechanism** on a given network, what's the **probability** that there will be **global spreading**?
2. If spreading does take off, how far will it go?
3. How do the **details** of the network affect the outcome?
4. How do the **details** of the spreading mechanism affect the outcome?
5. What if the **seed** is one or many nodes?

🧩 **Next up:** We'll look at some fundamental kinds of spreading on generalized random networks.

Global spreading condition

- 🧩 We need to find: ^[5]
- R = the average # of infected edges that one random infected edge brings about.
- 🧩 Call R the **gain ratio**.
- 🧩 Define B_{k1} as the probability that a node of degree k is infected by a single infected edge.

$$R = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot \underbrace{(k-1)}_{\substack{\# \text{ outgoing} \\ \text{infected} \\ \text{edges}}} \cdot \underbrace{B_{k1}}_{\substack{\text{Prob. of} \\ \text{infection}}} + \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot \underbrace{0}_{\substack{\# \text{ outgoing} \\ \text{infected} \\ \text{edges}}} \cdot \underbrace{(1-B_{k1})}_{\substack{\text{Prob. of} \\ \text{no infection}}}$$

Global spreading condition

- 🧩 **Cases 3, 4, 5, ...:** Now allow B_{k1} to depend on k
- 🧩 **Asymmetry:** Transmission along an edge depends on node's degree at other end.
- 🧩 Possibility: B_{k1} increases with k ... **unlikely**.
- 🧩 Possibility: B_{k1} is not monotonic in k ... **unlikely**.
- 🧩 Possibility: B_{k1} decreases with k ... **hmmm**.
- 🧩 $B_{k1} \searrow$ is a plausible representation of a simple kind of social contagion.
- 🧩 **The story:** More well connected people are harder to influence.

Global spreading condition

Example: $B_{k1} = 1/k$.

$$\mathbf{R} = \sum_{k=1}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1} = \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} \cdot \frac{1}{k}$$

$$= \sum_{k=1}^{\infty} \frac{P_k}{\langle k \rangle} \cdot (k-1) = 1 - \frac{1-P_0}{\langle k \rangle}$$

- Since \mathbf{R} is always less than 1, no spreading can occur for this mechanism.
- Decay of B_{k1} is too fast.
- Result is independent of degree distribution.

Threshold model on a network

- Interactions between individuals now represented by a network
- Network is **sparse**
- Individual i has k_i contacts
- Influence on each link is **reciprocal** and of **unit weight**
- Each individual i has a fixed threshold ϕ_i
- Individuals repeatedly poll contacts on network
- Synchronous, discrete time updating
- Individual i becomes active when number of active contacts $a_i \geq \phi_i k_i$
- Activation is permanent (SI)

Global spreading condition

The uniform threshold model global spreading condition:

$$\mathbf{R} = \sum_{k=1}^{\lfloor \frac{1}{\phi} \rfloor} (k-1) \cdot \frac{kP_k}{\langle k \rangle} > 1.$$

- As $\phi \rightarrow 1$, all nodes become resilient and $r \rightarrow 0$.
- As $\phi \rightarrow 0$, all nodes become vulnerable and the contagion condition matches up with the giant component condition.
- Key:** If we fix ϕ and then vary $\langle k \rangle$, we may see **two** phase transitions.
- Added to our standard giant component transition, we will see a cut off in spreading as nodes become more connected.

The most gullible

Vulnerables:

- Recall definition: individuals who can be activated by just one contact being active are **vulnerables**.
- The vulnerability condition for node i : $1/k_i \geq \phi_i$.
- Means # contacts $k_i \leq \lfloor 1/\phi_i \rfloor$.
- Key:** For global spreading events (cascades) on random networks, must have a **global component of vulnerables**^[15]
- For a uniform threshold ϕ , our global spreading condition tells us when such a component exists:

$$\mathbf{R} = \sum_{k=1}^{\lfloor \frac{1}{\phi} \rfloor} \frac{kP_k}{\langle k \rangle} \cdot (k-1) > 1.$$

Example random network structure:

- Ω_{crit} = critical mass = global vulnerable component
- Ω_{trig} = triggering component
- Ω_{final} = potential extent of spread
- Ω = entire network

$$\Omega_{crit} \subset \Omega_{trig}; \Omega_{crit} \subset \Omega_{final}; \text{ and } \Omega_{trig}, \Omega_{final} \subset \Omega.$$

Cascades on random networks

(n.b., $z = \langle k \rangle$)

- Largest vulnerable component = **critical mass**.
- Now have endogenous mechanism for spreading from an individual to the critical mass and then beyond.

- Time taken for cascade to spread through network. [15]
- Two phase transitions.

Social Contagion

Granovetter's Threshold model—recap

- Assumes deterministic response functions
- ϕ_* = threshold of an individual.
- $f(\phi_*)$ = distribution of thresholds in a population.
- $F(\phi_*)$ = cumulative distribution = $\int_{\phi'_*=0}^{\phi_*} f(\phi'_*) d\phi'_*$
- ϕ_t = fraction of people 'rioting' at time t .

Global spreading events on random networks [15]

$z = \langle k \rangle$

- Top curve:** final fraction infected if successful.
- Middle curve:** chance of starting a global spreading event (cascade).
- Bottom curve:** fractional size of vulnerable subcomponent. [15]

- Global spreading events occur only if size of vulnerable subcomponent > 0 .
- System is robust-yet-fragile just below upper boundary [3, 4, 14]
- 'Ignorance' facilitates spreading.

Cascade window for random networks

(n.b., $z = \langle k \rangle$)

- Outline of cascade window for random networks.

Social Sciences—Threshold models

- At time $t + 1$, fraction rioting = fraction with $\phi_* \leq \phi_t$.

-

$$\phi_{t+1} = \int_0^{\phi_t} f(\phi_*) d\phi_* = F(\phi_*)|_0^{\phi_t} = F(\phi_t)$$

- \Rightarrow Iterative maps of the unit interval $[0, 1]$.

Cascades on random networks

- Above lower phase transition

- Just below upper phase transition

Cascade window for random networks

Social Sciences—Threshold models

Action based on perceived behavior of others.

- Two states: S and I
- Recover now possible (SIS)
- ϕ = fraction of contacts 'on' (e.g., rioting)
- Discrete time, synchronous update (strong assumption!)
- This is a **Critical mass model**

Social Sciences—Threshold models

Threshold contagion on random networks

Three key pieces to describe analytically:

1. The fractional size of the largest subcomponent of vulnerable nodes, S_{vuln} .
 2. The chance of starting a global spreading event, $P_{\text{trig}} = S_{\text{trig}}$.
 3. The expected final size of any successful spread, S .
- n.b., the distribution of S is almost always bimodal.

Threshold contagion on random networks

We now have a generating function for the probability that a randomly chosen node is vulnerable and has degree k :

$$F_P^{(\text{vuln})}(x) = \sum_{k=0}^{\infty} P_k B_{k1} x^k.$$

The generating function for friends-of-friends distribution is similar to before:

$$F_R^{(\text{vuln})}(x) = \sum_{k=0}^{\infty} \frac{k P_k}{\langle k \rangle} B_{k1} x^{k-1} = \frac{\frac{d}{dx} F_P^{(\text{vuln})}(x)}{\frac{d}{dx} F_P^{(\text{vuln})}(x)|_{x=1}} = \frac{\frac{d}{dx} F_P^{(\text{vuln})}(x)}{F_R(1)}$$

Detail: We still have the underlying degree distribution involved in the denominator.

Threshold contagion on random networks

Functional relations for component size g.f.'s are almost the same ...

$$F_{\pi}^{(\text{vuln})}(x) = \frac{1 - F_P^{(\text{vuln})}(1) + x F_P^{(\text{vuln})}(F_{\rho}^{(\text{vuln})}(x))}{\text{central node is not vulnerable}}$$

$$F_{\rho}^{(\text{vuln})}(x) = \frac{1 - F_R^{(\text{vuln})}(1) + x F_R^{(\text{vuln})}(F_{\rho}^{(\text{vuln})}(x))}{\text{first node is not vulnerable}}$$

Can now solve as before to find

$$S_{\text{vuln}} = 1 - F_{\pi}^{(\text{vuln})}(1).$$

Threshold contagion on random networks

- First goal:** Find the largest component of vulnerable nodes.
- Recall that for finding the giant component's size, we had to solve:

$$F_{\pi}(x) = x F_P(F_{\rho}(x)) \text{ and } F_{\rho}(x) = x F_R(F_{\rho}(x))$$
- We'll find a similar result for the subset of nodes that are vulnerable.
- This is a node-based percolation problem.
- For a general monotonic threshold distribution $f(\phi)$, a degree k node is vulnerable with probability

$$B_{k1} = \int_0^{1/k} f(\phi) d\phi.$$

Threshold contagion on random networks

- Second goal:** Find probability of triggering largest vulnerable component.
- Assumption is **first node is randomly chosen**.
- Same set up as for vulnerable component except now we don't care if the initial node is vulnerable or not:

$$F_{\pi}^{(\text{trig})}(x) = x F_P(F_{\rho}^{(\text{vuln})}(x))$$

$$F_{\rho}^{(\text{vuln})}(x) = 1 - F_R^{(\text{vuln})}(1) + x F_R^{(\text{vuln})}(F_{\rho}^{(\text{vuln})}(x))$$

Solve as before to find $P_{\text{trig}} = S_{\text{trig}} = 1 - F_{\pi}^{(\text{trig})}(1)$.

Physical derivation of possibility and probability of global spreading:

- Possibility: binary indicator of phase. Global spreading events are either possible or can never happen.
- For random networks, global spreading possibility is understood as meaning a giant component of vulnerable nodes exists.
- Next: what's the probability that a randomly infected node will cause a global spreading event?
- Call this P_{trig} .
- As usual, it's all about edges and we need to first determine the probability that an infected edge leads to a global spreading event.
- Call this Q_{trig} .
- Later: Generalize to more complex networks involving assortativity of all kinds.

- Global spreading is possible if the fractional size S_{vuln} of the largest component of vulnerables is "giant".
- Interpret S_{vuln} as the probability a randomly chosen node is vulnerable and that infecting it leads to a global spreading event:
$$S_{\text{vuln}} = \sum_k P_k \cdot B_{k1} \cdot [1 - (1 - Q_{\text{trig}})^k] > 0.$$
- Amounts to having $Q_{\text{trig}} > 0$.
- Probability of global spreading differs only in that we don't care if the initial seed is vulnerable or not:
$$P_{\text{trig}} = S_{\text{trig}} = \sum_k P_k \cdot [1 - (1 - Q_{\text{trig}})^k]$$
- As for S_{vuln} , P_{trig} is non-zero when $Q_{\text{trig}} > 0$.

Triggering probability for single-seed global spreading events:

- Slight adjustment to the vulnerable component calculation.
$$S_{\text{trig}} = 1 - F_{\pi}^{(\text{trig})}(1) \text{ where } F_{\pi}^{(\text{trig})}(1) = 1 \cdot F_P(F_{\rho}^{(\text{vuln})}(1)).$$
- We play these cards: $F_{\rho}^{(\text{vuln})}(1) = 1 - Q_{\text{trig}}$ and $F_P(x) = \sum_{k=0}^{\infty} P_k x^k$ to arrive at
$$1 - S_{\text{trig}} = 1 + \sum_{k=0}^{\infty} P_k (1 - Q_{\text{trig}})^k.$$
- More scruffing around brings happiness:
$$S_{\text{trig}} = \sum_{k=0}^{\infty} P_k [1 - (1 - Q_{\text{trig}})^k].$$

Probability an infected edge leads to a global spreading event:

- Q_{trig} must satisfying a one-step recursion relation.
- Follow an infected edge and use three pieces:
 - Probability of reaching a degree k node is $Q_k = \frac{kP_k}{\langle k \rangle}$.
 - The node reached is vulnerable with probability B_{k1} .
 - At least one of the node's outgoing edges leads to a global spreading event = $1 - \text{probability no edges do so} = 1 - (1 - Q_{\text{trig}})^{k-1}$.
- Put everything together and solve for Q_{trig} :

$$Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot [1 - (1 - Q_{\text{trig}})^{k-1}].$$

Connection to generating function results:

- We found that $F_{\rho}^{(\text{vuln})}(1)$ —the probability that a random edge leads to a finite vulnerable component—satisfies
$$F_{\rho}^{(\text{vuln})}(1) = 1 - F_R^{(\text{vuln})}(1) + 1 \cdot F_R^{(\text{vuln})}(F_{\rho}^{(\text{vuln})}(1)).$$
- We set $F_{\rho}^{(\text{vuln})}(1) = 1 - Q_{\text{trig}}$ and deploy $F_R^{(\text{vuln})}(x) = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} B_{k1} x^{k-1}$ to find
$$1 - Q_{\text{trig}} = 1 - \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} B_{k1} + \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} B_{k1} (1 - Q_{\text{trig}})^{k-1}.$$
- Some breathless algebra it all matches:
$$Q_{\text{trig}} = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot [1 - (1 - Q_{\text{trig}})^{k-1}].$$

Connection to simple gain ratio argument:

- Earlier, we showed the global spreading condition follows from the gain ratio $\mathbf{R} > 1$:
$$\mathbf{R} = \sum_{k=0}^{\infty} \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1} > 1.$$
- We would very much like to see that $\mathbf{R} > 1$ matches up with $Q_{\text{trig}} > 0$.
- It really would be just so totally awesome.
- Must come from our basic edge triggering probability equation:
$$Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot [1 - (1 - Q_{\text{trig}})^{k-1}].$$
- When does this equation have a solution $0 < Q_{\text{trig}} \leq 1$?
- We need to find out what happens as $Q_{\text{trig}} \rightarrow 0$.^[9]

Good things about our equation for Q_{trig} :

- $Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot [1 - (1 - Q_{\text{trig}})^{k-1}] = f(Q_{\text{trig}}; P_k, B_{k1})$
- $Q_{\text{trig}} = 0$ is always a solution.
- Spreading occurs if a second solution exists for which $0 < Q_{\text{trig}} \leq 1$.
- Given P_k and B_{k1} , we can use any kind of root finder to solve for Q_{trig} , but ...
- The function f increases monotonically with Q_{trig} .
- We can therefore use an iterative cobwebbing approach to find the solution:
$$Q_{\text{trig}}^{(n+1)} = f(Q_{\text{trig}}^{(n)}; P_k, B_{k1}).$$
- Start with a suitably small seed $Q_{\text{trig}}^{(1)} > 0$ and iterate while rubbing hands together.

Fractional size of the largest vulnerable component:

- The generating function approach gave $S_{\text{vuln}} = 1 - F_{\pi}^{(\text{vuln})}(1)$ where
$$F_{\pi}^{(\text{vuln})}(1) = 1 - F_P^{(\text{vuln})}(1) + 1 \cdot F_P^{(\text{vuln})}(F_{\rho}^{(\text{vuln})}(1)).$$
- Again using $F_{\rho}^{(\text{vuln})}(1) = 1 - Q_{\text{trig}}$ along with $F_P^{(\text{vuln})}(x) = \sum_{k=0}^{\infty} P_k B_{k1} x^k$, we have:
$$1 - S_{\text{vuln}} = 1 - \sum_{k=0}^{\infty} P_k B_{k1} + \sum_{k=0}^{\infty} P_k B_{k1} (1 - Q_{\text{trig}})^k.$$
- Excited scrabbling about gives us, as before:
$$S_{\text{vuln}} = \sum_{k=0}^{\infty} P_k B_{k1} [1 - (1 - Q_{\text{trig}})^k].$$

For $Q_{\text{trig}} \rightarrow 0^+$, equation tends towards

$$Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot [\lambda + (\lambda + (k-1)Q_{\text{trig}} + \dots)]$$

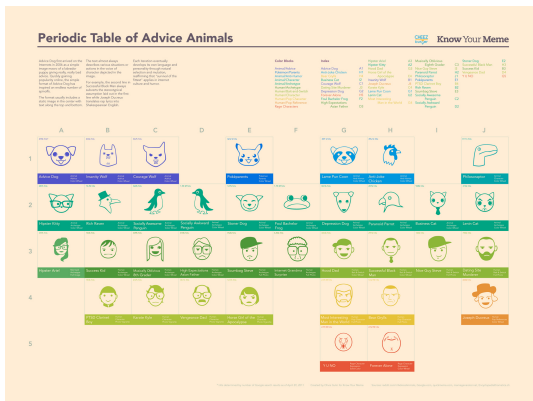

$$\Rightarrow Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot (k-1)Q_{\text{trig}}$$

$$\Rightarrow 1 = \sum_k \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1}$$

Only defines the phase transition points (i.e., $\mathbf{R} = 1$).

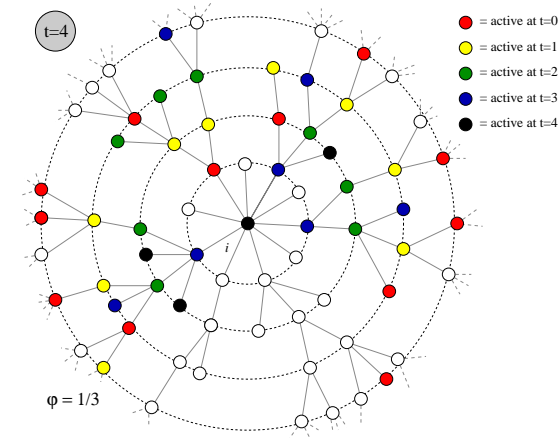

Inequality?

Meme species:

More here at <http://knowyourmeme.com>

Expected size of spread

Again take $Q_{\text{trig}} \rightarrow 0^+$, but keep next higher order term:

$$Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot \left[\lambda + (\lambda + (k-1)Q_{\text{trig}} - \binom{k-1}{2} Q_{\text{trig}}^2) \right]$$

$$\Rightarrow Q_{\text{trig}} = \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot \left[(k-1)Q_{\text{trig}} - \binom{k-1}{2} Q_{\text{trig}}^2 \right]$$

$$\Rightarrow \sum_k \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1} = 1 + \sum_k \frac{kP_k}{\langle k \rangle} \cdot B_{k1} \cdot \binom{k-1}{2} Q_{\text{trig}}$$

We have $Q_{\text{trig}} > 0$ if $\sum_k \frac{kP_k}{\langle k \rangle} \cdot (k-1) \cdot B_{k1} > 1$.

Repeat: Above is a mathematical connection between two physically derived equations.

From this connection, we don't know anything about a gain ratio \mathbf{R} or how to arrange the pieces.

Expected size of spread

Idea:

- Randomly turn on a fraction ϕ_0 of nodes at time $t = 0$
- Capitalize on local branching network structure of random networks (again)
- Now think about what must happen for a specific node i to become active at time t :
 - $t = 0$: i is one of the seeds (prob = ϕ_0)
 - $t = 1$: i was not a seed but enough of i 's friends switched on at time $t = 0$ so that i 's threshold is now exceeded.
 - $t = 2$: enough of i 's friends and friends-of-friends switched on at time $t = 0$ so that i 's threshold is now exceeded.
 - $t = n$: enough nodes within n hops of i switched on at $t = 0$ and their effects have propagated to reach i .

Expected size of spread

Notes:

- Calculations presume nodes do not become inactive (strong restriction, liftable)
- Not just for threshold model—works for a wide range of contagion processes.
- We can analytically determine the entire time evolution, not just the final size.
- We can in fact determine $\Pr(\text{node of degree } k \text{ switches on at time } t)$.
- Even more, we can compute: $\Pr(\text{specific node } i \text{ switches on at time } t)$.
- Asynchronous updating can be handled too.

Threshold contagion on random networks

- Third goal:** Find expected fractional size of spread.
- Not obvious even for uniform threshold problem.
- Difficulty is in figuring out if and when nodes that need ≥ 2 hits switch on.
- Problem solved for infinite seed case by Gleeson and Cahalane: "Seed size strongly affects cascades on random networks," Phys. Rev. E, 2007.^[7]
- Developed further by Gleeson in "Cascades on correlated and modular random networks," Phys. Rev. E, 2008.^[6]

Expected size of spread

Expected size of spread

Pleasantness:

- Taking off from a single seed story is about **expansion** away from a node.
- Extent of spreading story is about **contraction** at a node.

Expected size of spread

- Notation:** $\phi_{k,t} = \Pr(\text{a degree } k \text{ node is active at time } t)$.
- Notation:** $B_{kj} = \Pr(\text{a degree } k \text{ node becomes active if } j \text{ neighbors are active})$.
- Our starting point: $\phi_{k,0} = \phi_0$.
- $\binom{k}{j} \phi_0^j (1 - \phi_0)^{k-j} = \Pr(j \text{ of a degree } k \text{ node's neighbors were seeded at time } t = 0)$.
- Probability a degree k node was a seed at $t = 0$ is ϕ_0 (as above).
- Probability a degree k node was not a seed at $t = 0$ is $(1 - \phi_0)$.
- Combining everything, we have:

$$\phi_{k,1} = \phi_0 + (1 - \phi_0) \sum_{j=0}^k \binom{k}{j} \phi_0^j (1 - \phi_0)^{k-j} B_{kj}$$

Expected size of spread

- For general t , we need to know the probability an edge coming into a degree k node at time t is active.
- Notation:** call this probability θ_t .
- We already know $\theta_0 = \phi_0$.
- Story analogous to $t = 1$ case. For specific node i :

$$\phi_{i,t+1} = \phi_0 + (1 - \phi_0) \sum_{j=0}^{k_i} \binom{k_i}{j} \theta_t^j (1 - \theta_t)^{k_i-j} B_{k_i j}$$

- Average over all nodes with degree k to obtain expression for ϕ_{t+1} :

$$\phi_{t+1} = \phi_0 + (1 - \phi_0) \sum_{k=0}^{\infty} P_k \sum_{j=0}^k \binom{k}{j} \theta_t^j (1 - \theta_t)^{k-j} B_{kj}$$

- So we need to compute $\theta_t \dots$ massive excitement...

Expected size of spread

First connect θ_0 to θ_1 :

- $\theta_1 = \phi_0 +$

$$(1 - \phi_0) \sum_{k=1}^{\infty} \frac{k P_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_0^j (1 - \theta_0)^{k-1-j} B_{kj}$$

- $\frac{k P_k}{\langle k \rangle} = Q_k = \Pr(\text{edge connects to a degree } k \text{ node})$.
- $\sum_{j=0}^{k-1}$ piece gives $\Pr(\text{degree node } k \text{ activates if } j \text{ of its } k-1 \text{ incoming neighbors are active})$.
- ϕ_0 and $(1 - \phi_0)$ terms account for state of node at time $t = 0$.
- See this all generalizes to give θ_{t+1} in terms of $\theta_t \dots$

Expected size of spread

Two pieces: edges first, and then nodes

$$1. \theta_{t+1} = \underbrace{\phi_0}_{\text{exogenous}} + \underbrace{(1 - \phi_0) \sum_{k=1}^{\infty} \frac{k P_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_t^j (1 - \theta_t)^{k-1-j} B_{kj}}_{\text{social effects}}$$

with $\theta_0 = \phi_0$.

$$2. \phi_{t+1} = \underbrace{\phi_0}_{\text{exogenous}} + \underbrace{(1 - \phi_0) \sum_{k=0}^{\infty} P_k \sum_{j=0}^k \binom{k}{j} \theta_t^j (1 - \theta_t)^{k-j} B_{kj}}_{\text{social effects}}$$

Comparison between theory and simulations

From Gleeson and Cahalane [7]

- Pure random networks with simple threshold responses
- $R = \text{uniform threshold (our } \phi_*)$; $z = \text{average degree}$; $\rho = \phi$; $q = \theta$; $N = 10^5$.
- $\phi_0 = 10^{-3}, 0.5 \times 10^{-2}$, and 10^{-2} .
- Cascade window is for $\phi_0 = 10^{-2}$ case.
- Sensible expansion of cascade window as ϕ_0 increases.

Notes:

- Retrieve cascade condition for spreading from a single seed in limit $\phi_0 \rightarrow 0$.
- Depends on map $\theta_{t+1} = G(\theta_t; \phi_0)$.
- First: if self-starters are present, some activation is assured:

$$G(0; \phi_0) = \sum_{k=1}^{\infty} \frac{k P_k}{\langle k \rangle} \bullet B_{k0} > 0.$$

meaning $B_{k0} > 0$ for at least one value of $k \geq 1$.

- If $\theta = 0$ is a fixed point of G (i.e., $G(0; \phi_0) = 0$) then spreading occurs for a small seed if

$$G'(0; \phi_0) = \sum_{k=0}^{\infty} \frac{k P_k}{\langle k \rangle} \bullet (k-1) \bullet B_{k1} > 1.$$

Insert assignment question [7]

Notes:

In words:

- If $G(0; \phi_0) > 0$, spreading must occur because some nodes turn on for free.
- If G has an **unstable fixed point** at $\theta = 0$, then cascades are also always possible.

Non-vanishing seed case:

- Cascade condition is more complicated for $\phi_0 > 0$.
- If G has a **stable fixed point** at $\theta = 0$, and an **unstable fixed point** for some $0 < \theta_* < 1$, then for $\theta_0 > \theta_*$, spreading takes off.
- Tricky point: G depends on ϕ_0 , so as we change ϕ_0 , we also change G .

General fixed point story:

- Given $\theta_0 (= \phi_0)$, θ_{∞} will be the nearest stable fixed point, either above or below.
- n.b., adjacent fixed points must have opposite stability types.
- Important:** Actual form of G depends on ϕ_0 .
- Important:** ϕ_t can only increase monotonically so ϕ_0 must shape G so that ϕ_0 is at or above an unstable fixed point.
- First reason: $\phi_1 \geq \phi_0$.
- Second: $G'(\theta; \phi_0) \geq 0, 0 \leq \theta \leq 1$.

Interesting behavior:

From Gleeson and Cahalane [7]

- Now allow thresholds to be distributed according to a Gaussian with mean R .
- $R = 0.2, 0.362$, and 0.38 ; $\sigma = 0.2$.
- $\phi_0 = 0$ but some nodes have thresholds ≤ 0 so effectively $\phi_0 > 0$.
- Now see a (nasty) discontinuous phase transition for low $\langle k \rangle$.

Interesting behavior:

- Plots of stability points for $\theta_{t+1} = G(\theta_t; \phi_0)$.
- n.b.: 0 is not a fixed point here: $\theta_0 = 0$ always takes off.
- Top to bottom: $R = 0.35, 0.371, \text{ and } 0.375$.
- Saddle node bifurcations appear and merge (b and c).

From Gleeson and Cahalane [7]

What's happening:

Fixed points slip above and below the $\theta_{t+1} = \theta_t$ line:

Time-dependent solutions

Synchronous update

Done: Evolution of ϕ_t and θ_t given exactly by the maps we have derived.

Asynchronous updates

- Update nodes with probability α .
- As $\alpha \rightarrow 0$, updates become effectively independent.
- Now can talk about $\phi(t)$ and $\theta(t)$.
