 The Unsolved Allometry Theoricides.

A **power law** relates two variables x and y as follows:

$$y = cx^{\alpha}$$

α is the **scaling exponent** (or just exponent)

α can be any number in principle but we will find various restrictions.

c is the **prefactor** (which can be important!)

 *Medium quality:* scaling persists over three or more orders of magnitude for **only one variable** and at least one for **the other**.

Good scaling:

General rules of thumb:

High quality: scaling persists over three or more orders of magnitude for **each variable**.

Medium quality: scaling persists over three or more orders of magnitude for **only one variable** and at least one for **the other**.

Very dubious: scaling 'persists' over less than an order of magnitude for **both variables**.

Unconvincing scaling:

Average walking speed as a function of city population:

Two problems:

1. use of natural log, and
2. minute variation in dependent variable.

from Bettencourt et al. (2007) ^[4]; otherwise totally great—more later.

Compare with $y = ce^{-\lambda x}$:

 If we rescale x as $x = rx'$, then

$$y = ce^{-\lambda rx'}$$

 Original form cannot be recovered.

 **Scale matters** for the exponential.

More on $y = ce^{-\lambda x}$:

 Say $x_0 = 1/\lambda$ is the **characteristic scale**.

 For $x \gg x_0$, y is small,
while for $x \ll x_0$, y is large.

“Scaling in athletic world records”

Savaglio and Carbone,

Nature, **404**, 244, 2000. [34]

Mean speed $\langle s \rangle$ decays with race time τ :

$$\langle s \rangle \sim \tau^{-\beta}$$

Figure 1 Plots of world record mean speeds against the record time (at November 1999). **a,b**, Running, and **c,d**, swimming records: for men (**a,c**), we consider 11 races (200 m, 400 m, 800 m, 1,600 m, 1,500 m, the mile, 3,000 m, 5,000 m, 10,000 m, 1 hour, and marathon); the same races are considered for women (**b,d**), apart from the 1 hour race. Lines represent the best fits. The scaling exponents β and characteristic times τ^* of the breakpoints are shown; characteristic times have been determined by using a χ^2 minimization on a broken power law. Triangles in **a,b** represent the 100 m race, which is excluded from the analysis because the mean speed is strongly affected by the standing start of athletes.

EEK: Small scaling regimes

“Scaling in athletic world records”

Savaglio and Carbone,

Nature, **404**, 244, 2000. [34]

Mean speed $\langle s \rangle$ decays with race time τ :

$$\langle s \rangle \sim \tau^{-\beta}$$

Break in scaling at around $\tau \simeq 150\text{--}170$ seconds

Figure 1 Plots of world record mean speeds against the record time (at November 1999). **a,b**, Running, and **c,d**, swimming records: for men (**a,b**), we consider 11 races (200 m, 400 m, 800 m, 1,600 m, 1,500 m, the mile, 3,000 m, 5,000 m, 10,000 m, 1 hour, and marathon); the same races are considered for women (**c,d**), apart from the 1 hour race. Lines represent the best fits. The scaling exponents β and characteristic times τ^* of the breakpoints are shown; characteristic times have been determined by using a χ^2 minimization on a broken power law. Triangles in **a,b** represent the 100 m race, which is excluded from the analysis because the mean speed is strongly affected by the standing start of athletes.

EEK: Small scaling regimes

“Scaling in athletic world records”

Savaglio and Carbone,

Nature, **404**, 244, 2000. [34]

Mean speed $\langle s \rangle$ decays with race time τ :

$$\langle s \rangle \sim \tau^{-\beta}$$

Break in scaling at around $\tau \simeq 150\text{--}170$ seconds

Anaerobic-aerobic transition

Figure 1 Plots of world record mean speeds against the record time (at November 1999). **a,b**, Running, and **c,d**, swimming records; for men (**a,c**), we consider 11 races (200 m, 400 m, 800 m, 1,600 m, 1,500 m, the mile, 3,000 m, 5,000 m, 10,000 m, 1 hour, and marathon); the same races are considered for women (**b,d**), apart from the 1 hour race. “Athletics: Momentous sprint at the 2156 Olympics?” [↗](#)
 Tatem et al.,
 Nature, **431**, 525–525, 2004. ^[36]

Linear extrapolation for the 100 metres:

Figure 1 The winning Olympic 100-metre sprint times for men (blue points) and women (red points), with superimposed best-fit linear regression lines (solid black lines) and coefficients of determination. The regression lines are extrapolated (broken blue and red lines for men and women, respectively) and 95% confidence intervals (dotted black lines) based on the available points are superimposed. The projections intersect just before the 2156 Olympics, when the winning women's 100-metre sprint time of 8.079 s will be faster than the men's at 8.098 s.

Tatem: [↗](#) “If I’m wrong anyone is welcome to come and question me about the result after the 2156 Olympics.”

 To drive nails in, posit resistive force $\propto$ nail circumference = πd .

 Match forces independent of nail size: $d^4/\ell^2 \propto d$.

 Leads to $d \propto \ell^{2/3}$.

 Argument made by Galileo ^[11] in 1638 in “Discourses on Two New Sciences.”  Also, see here. 

 Another smart person’s contribution: Euler, 1757 

 Also see McMahon, “Size and Shape in Biology,” Science, 1973. ^[25]

Rowing: Speed $\propto$ (number of rowers)^{1/9}

Shell dimensions and performances.

No. of oarsmen	Modifying description	Length, <i>l</i> (m)	Beam, <i>b</i> (m)	<i>l/b</i>	Boat mass per oarsman (kg)	Time for 2000 m (min)

Scaling in elementary laws of physics:

Inverse-square law of gravity and Coulomb's law:

$$F \propto \frac{m_1 m_2}{r^2} \quad \text{and} \quad F \propto \frac{q_1 q_2}{r^2}.$$

Force is diminished by expansion of space away from source.

Scaling in elementary laws of physics:

Inverse-square law of gravity and Coulomb's law:

$$F \propto \frac{m_1 m_2}{r^2} \quad \text{and} \quad F \propto \frac{q_1 q_2}{r^2}.$$

Force is diminished by expansion of space away from source.

The square is $d - 1 = 3 - 1 = 2$, the dimension of a sphere's surface.

Scaling in elementary laws of physics:

 Inverse-square law of gravity and Coulomb's law:

$$F \propto \frac{m_1 m_2}{r^2} \quad \text{and} \quad F \propto \frac{q_1 q_2}{r^2}.$$

 Force is diminished by expansion of space away from source.

 The square is $d - 1 = 3 - 1 = 2$, the dimension of a sphere's surface.

 We'll see a gravity law applies for a range of human phenomena.

A nullspace equation: $\mathbf{A}\vec{x} = \vec{0}$.

Number of dimensionless parameters = Dimension of null space = $n - r$ where n is the number of columns of $\mathbf{A}$ and r is the rank of $\mathbf{A}$.

Here: $n = 4$ and $r = 3 \rightarrow F(\pi_1) = 0 \rightarrow \pi_1 = \text{const.}$

In general: Create a matrix $\mathbf{A}$ where ij th entry is the power of dimension i in the j th variable, and solve by row reduction to find basis null vectors.

Well, of course there are matrices:

Thrillingly, we have:

$$\mathbf{A}\vec{x} = \begin{bmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -2 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

A nullspace equation: $\mathbf{A}\vec{x} = \vec{0}$.

Number of dimensionless parameters = Dimension of null space = $n - r$ where n is the number of columns of $\mathbf{A}$ and r is the rank of $\mathbf{A}$.

Here: $n = 4$ and $r = 3 \rightarrow F(\pi_1) = 0 \rightarrow \pi_1 = \text{const.}$

In general: Create a matrix $\mathbf{A}$ where ij th entry is the power of dimension i in the j th variable, and solve by row reduction to find basis null vectors.

We (you) find: $\pi_1 = \ell/g\tau^2 = \text{const.}$

“Urban scaling and its deviations: Revealing the structure of wealth, innovation and crime across cities”

Bettencourt et al.,
PLoS ONE, 5, e13541, 2010. ^[5]

Comparing city features across populations:

Cities = Metropolitan Statistical Areas (MSAs)

Story: Fit scaling law and examine residuals

Does a city have more or less crime than expected when normalized for population?

Figure 1. Urban Agglomeration effects result in per capita nonlinear scaling of urban metrics. Subtracting these effects produces a truly local measure of urban dynamics and a reference scale for ranking cities. a) A typical superlinear scaling law (solid line): Gross Metropolitan Product of US MSAs in 2006 (red dots) vs. population; the slope of the solid line has exponent, $\beta = 1.126$ (95% CI [1.101, 1.149]). b) Histogram showing frequency of residuals, (SAMIs, see Eq. (2)); the statistics of residuals is well described by a Laplace distribution (red line). Scale independent ranking (SAMIs) for US MSAs by c) personal income and d) patenting (red denotes above average performance, blue below). For more details see Text S1, Table S1 and Figure S1.

A possible theoretical explanation?

“The origins of scaling in cities”

Non-simple scaling for death:

“Statistical signs of social influence on suicides” 

Melo et al.,

Scientific Reports, **4**, 6239, 2014. ^[27]

Bettencourt *et al.*'s initial work suggested social phenomena would follow superlinear scaling (wealth, crime, disease)

Homicide, traffic, and suicide ^[10] all tied to social context in complex, different ways.

For cities in Brazil, Melo *et al.* show:

Homicide appears to follow superlinear scaling
($\beta = 1.24 \pm 0.01$)

Figure 1 | Scaling relations for homicides, traffic accidents, and suicides for the year of 2009 in Brazil. The small circles show the total number of deaths by (a) homicides (red), (b) traffic accidents (blue), and (c) suicides (green) vs the population of each city. Each graph represents only one urban indicator, and the solid gray line indicate the best fit for a power-law relation, using OLS regression, between the average total number of deaths and the city size (population). To reduce the fluctuations we also performed a Nadaraya-Watson kernel regression^{17,18}. The dashed lines show the 95% confidence band for the Nadaraya-Watson kernel regression. The ordinary least-squares (OLS)¹⁹ fit to the Nadaraya-Watson kernel regression applied to the data on homicides in (a) reveals an allometric exponent $\beta = 1.24 \pm 0.01$, with a 95% confidence interval estimated by bootstrap. This is compatible with previous results obtained for U.S.² that also indicate a super-linear scaling relation with population and an exponent $\beta = 1.16$. Using the same procedure, we find $\beta = 0.99 \pm 0.02$ and 0.84 ± 0.02 for the numbers of deaths in traffic accidents (b) and suicides (c), respectively. The values of the Pearson correlation coefficients ρ associated with these scaling relations are shown in each plot. This non-linear behavior observed for homicides and suicides certainly reflects the complexity of human social relations and strongly suggests that the topology of the social network plays an important role on the rate of these events. (d) The solid lines show the Nadaraya-Watson kernel regression rate of deaths (total number of deaths divided by the population of a city) for each urban indicator, namely, homicides (red), traffic accidents (blue), and suicides (green). The dashed lines represent the 95% confidence bands. While the rate of fatal traffic accidents remains approximately invariant, the rate of homicides systematically increases, and the rate of suicides decreases with population.

Dynamics (Brazil):

Figure 2 | Temporal evolution of allometric exponent β for homicides (red squares), deaths in traffic accidents (blue circles), and suicides (green diamonds). Time evolution of the power-law exponent β for each behavioral urban indicator in Brazil from 1992 to 2009. We can see that the non-linear behavior for homicides and suicides are robust for this 19 years period, and for the traffic accidents the exponent remain close to 1.0.

US data:

Density of public and private facilities:

$$\rho_{\text{fac}} \propto \rho_{\text{pop}}^{\alpha}$$

Left plot: ambulatory hospitals in the U.S.

Right plot: public schools in the U.S.

“Pattern in escalations in insurgent and terrorist activity”

Johnson et al.,
Science, **333**, 81–84, 2011. ^[16]

Fig. 1. (A) Schematic timeline of successive fatal days shown as vertical bars. τ_1 is the time interval between the first two fatal days, labeled 0 and 1. **(B)** Successive time intervals τ_n between days with IED fatalities in the Afghanistan province of Kandahar (squares). On this log-log plot, the best-fit power-law progress curve is by definition a straight (blue) line with slope $-b$ (b is an escalation rate). **(C)** The solid blue line shows best linear fit through progress-curve parameter values τ_1 and b for individual Afghanistan provinces for all hostile fatalities (all coalition military fatalities attributed to insurgent activity). The green dashed line shows value $b = 0.5$, which is the situation in which there are no correlations. The subset of fatalities recorded in casualties as “southern Afghanistan” is shown as a separate region because of their likely connection to operations near the Pakistan border.

Escalation: $\tau_n \sim \tau_1 n^{-b}$

b = scaling exponent
(escalation rate)

Interevent time τ_n between
fatal attacks $n - 1$ and n
(binned by days)

The **more common** a verb is, the **more resilient** it is to change.

Irregular verbs

Table 1 | The 177 irregular verbs studied

Frequency	Verbs	Regularization (%)	Half-life (yr)
10 ⁻¹ –1	be, have	0	38,800
10 ⁻² –10 ⁻¹	come, do, find, get, give, go, know, say, see, take, think	0	14,400
10 ⁻³ –10 ⁻²	begin, break, bring, buy, choose, draw, drink, drive, eat, fall, fight, forget, grow, hang, help , hold, leave, let, lie, lose, reach , rise, run, seek, set, shake, sit, sleep, speak, stand, teach, throw, understand, walk , win, work , write	10	5,400
10 ⁻⁴ –10 ⁻³	arise, bake , bear, beat, bind, bite, blow, bow , burn, burst, carve , chew , climb , cling, creep, dare , dig, drag , flee, float , flow , fly, fold , freeze, grind, leap, lend, lock , melt , reckon , ride, rush , shape , shine, shoot, shrink, sigh , sing, sink, slide, slip , smoke , spin, spring, starve , steal, step , stretch , strike, stroke , suck , swallow , swear, sweep, swim, swing, tear, wake, wash , weave, weep, weigh , wind, yell , yield	43	2,000
10 ⁻⁵ –10 ⁻⁴	bark , bellow, bid, blend , braid, brew, cleave, cringe, crow, dive, drip, fare, fret, glide, gnaw, grip, heave, knead, low, milk, mourn, mow, prescribe , redde n, reek, row, scrape, seethe , shear, shed, shove , slay, slit, smite , sow, span, spurn , sting, stink, strew, stride, swell, tread , uproot, wade , warp, wax, wield , wring, writhe	72	700
10 ⁻⁶ –10 ⁻⁵	bide , chide, delve, flay, hew, rue, shrive, slink, snip , spew, sup, wreak	91	300

177 Old English irregular verbs were compiled for this study. These are arranged according to frequency bin, and in alphabetical order within each bin. Also shown is the percentage of verbs in each bin that have regularized. The half-life is shown in years. Verbs that have regularized are indicated in red. As we move down the list, an increasingly large fraction of the verbs are red; the frequency-dependent regularization of irregular verbs becomes immediately apparent.

Red = regularized

Estimates of half-life for regularization ($\propto f^{1/2}$)

‘Wed’ is next to go.

-ed is the winning rule...

But ‘snuck’ is sneaking up on sneaked. [\[29\]](#)

‘When the group moved to California to become part of Lucasfilm, we got close to making a computer-animated movie again in the mid-1980s – this time about a monkey with godlike powers but a missing prefrontal cortex. We had a sponsor, a story treatment, and a marketing survey. We were prepared to make a screen test: Our hot young animator John Lasseter had sketched numerous studies of the hero monkey and had the sponsor salivating over a glass-dragon protagonist.’

“But when it came time to harden the deal and run the numbers for the contracts, I discovered to my dismay that computers were still too slow: The projected production cost was too high and the computation time way too long. We had to back out of the deal. This time, we did know enough detail to correctly apply Moore's Law – and it told us that we had to wait another five years to start making the first movie. And sure enough, five years later Disney approached us to make Toy Story.”

Types and Tokens:

 In linguistics, words are described on the two levels of types and tokens  ^[32].

 In semiotics, signs can be thought of having two components of the signified and the signifier .

Example:

 Types are 1-grams , e.g., ‘!’, ‘the’, ‘love’, and ‘spork’.¹⁰

 Tokens are 1-grams as written down.

¹⁰Linguists have a long history of not agreeing on what a word is .

Language:

1. Type: A defined word.
2. Thing (token): An instance of spoken or printed word.
3. Number or Frequency (counts of tokens).
4. Experience: Listening to others, reading a book.

Language:

1. Type: A defined word.
2. Thing (token): An instance of spoken or printed word.
3. Number or Frequency (counts of tokens).
4. Experience: Listening to others, reading a book.

Atoms:

1. Type: Atom
2. Thing: Element (stuff made of a given atom; e.g., gold)
3. Measure: Mass; could be Number.
4. Experience: Atomic bonds.

Water:

1. Type: Water molecule, H^2O .
2. Thing: Water.
3. Measure: Volume (liters, gallons); given pressure and temperature, equivalent to Number (counts of molecules) and then Mass.
4. Experience: Rain.

Water:

1. Type: Water molecule, H^2O .
2. Thing: Water.
3. Measure: Volume (liters, gallons); given pressure and temperature, equivalent to Number (counts of molecules) and then Mass.
4. Experience: Rain.

Biology:

Water:

1. Type: Water molecule, H^2O .
2. Thing: Water.
3. Measure: Volume (liters, gallons); given pressure and temperature, equivalent to Number (counts of molecules) and then Mass.
4. Experience: Rain.

Biology:

Example type: The species *Ornithorhynchus anatinus*, the platypus.

Water:

Example type: Corporation.

Things: The publicly traded companies of Apple and Microsoft.

Measure: Market capitalization.

Experience: Being sued by Microsoft.

Apple and Microsoft may be viewed as components of the publicly-owned corporate world.

The sizes of corporations may be broken down into many rankable dimensions such as annual revenue or number of employees worldwide.

Moneyspace:

- Example type: Corporation.
 - Things: The publicly traded companies of Apple and Microsoft.
 - Measure: Market capitalization.
 - Experience: Being sued by Microsoft.
-
- Apple and Microsoft may be viewed as components of the publicly-owned corporate world.
 - The sizes of corporations may be broken down into many rankable dimensions such as annual revenue or number of employees worldwide.
 - In principle, market capitalization represents a kind of current collective belief in terms of money.

Sizes and Rankings:

Sizes and Rankings:

 We will often consider systems where each component type τ has at least one measurable—and hence rankable—‘size’ s_τ .

Sizes and Rankings:

-  We will often consider systems where each component type τ has at least one measurable—and hence rankable—‘size’ s_τ .
-  Perceived size is a combination of Measure (what exists) and Experience (what is measured).

Sizes and Rankings:

-  We will often consider systems where each component type τ has at least one measurable—and hence rankable—‘size’ s_τ .
-  Perceived size is a combination of Measure (what exists) and Experience (what is measured).
-  Important: We may also have rankings where we do not know the underlying ‘size’ (e.g., book/thing sales on Amazon).

Three examples which show some of the range of what ‘size’ can mean:

1. Size for a word in a corpus means the number of indistinguishable instances of that word (many identical entites—tokens);
