What's the best way to distribute stuff?

- ▶ Stuff = medical services, energy, people,
- ▶ **Some** fundamental network problems:
 1. Distribute stuff from a **single source** to **many sinks**
 2. Distribute stuff from **many sources** to many sinks
 3. **Redistribute** stuff between nodes that are both sources and sinks
- ▶ Supply and Collection are equivalent problems

Optimization approaches

Cardiovascular networks:

- ▶ Murray's law (1926) connects branch radii at forks: [8]

$$r_0^3 = r_1^3 + r_2^3$$

where r_0 = radius of main branch
and r_1 and r_2 are radii of sub-branches

- ▶ Calculation assumes Poiseuille flow
- ▶ Holds up well for outer branchings of blood networks
- ▶ Also found to hold for trees
- ▶ Use hydraulic equivalent of Ohm's law:

$$\Delta p = \Phi Z \Leftrightarrow V = IR$$

where Δp = pressure difference, Φ = flux

Cardiovascular networks:

- ▶ Fluid mechanics: Poiseuille impedance for smooth flow in a tube of radius r and length ℓ :

$$Z = \frac{8\eta\ell}{\pi r^4}$$

where η = dynamic viscosity

- ▶ Power required to overcome impedance:

$$P_{\text{drag}} = \Phi \Delta p = \Phi^2 Z$$

- ▶ Also have rate of energy expenditure in maintaining blood:

$$P_{\text{metabolic}} = cr^2\ell$$

where c is a metabolic constant.

[Introduction](#)[Optimal branching](#)[Murray meets Tokunaga](#)[Single Source](#)[History](#)[Reframing the question](#)[Minimal volume calculation](#)[Blood networks](#)[River networks](#)[Distributed Sources](#)[Facility location](#)[Size-density law](#)[Cartograms](#)[References](#)

Aside on P_{drag}

- ▶ Work done = $F \cdot d$ = energy transferred by force F
- ▶ Power = rate work is done = $F \cdot v$
- ▶ ΔP = Force per unit area
- ▶ Φ = Volume per unit time
= cross-sectional area \cdot velocity
- ▶ So $\Phi \Delta P$ = Force \cdot velocity

Murray's law:

- ▶ Total power (cost):

$$P = P_{\text{drag}} + P_{\text{metabolic}} = \Phi^2 \frac{8\eta\ell}{\pi r^4} + cr^2\ell$$

- ▶ Observe power increases linearly with ℓ
- ▶ But r 's effect is nonlinear:
 - ▶ increasing r makes flow easier **but increases metabolic cost** (as r^2)
 - ▶ decreasing r decrease metabolic cost **but impedance goes up** (as r^{-4})

Frame 9/85

Murray's law:

- ▶ So we now have:

$$\Phi = kr^3$$

- ▶ Flow rates at each branching have to add up (else our organism is in serious trouble...):

$$\Phi_0 = \Phi_1 + \Phi_2$$

where again 0 refers to the main branch and 1 and 2 refers to the offspring branches

- ▶ All of this means we have a groovy cube-law:

$$r_0^3 = r_1^3 + r_2^3$$

Frame 19/85

Geometric argument

- ▶ Consider **one source supplying many sinks** in a d dimensional volume
- ▶ Material draw by sinks is invariant.
- ▶ Assume some cap on flow speed of material, v_{\max}
- ▶ See network as a bundle of virtual vessels:

- ▶ **The right question:** how does number of sustainable sinks N_{sinks} scale with volume V for the most efficient network design?
- ▶ Or: what is highest α for $N_{\text{sinks}} \propto V^\alpha$?

Introduction

Optimal branching

Murray meets Tokunaga

Single Source

History

Reframing the question

Minimal volume calculation

Blood networks

River networks

Distributed Sources

Facility location

Size-density law

Cartograms

References

Geometric argument

- ▶ Best case: lengths of virtual vessels $\propto r$.
- ▶ Worst case: lengths of virtual vessels $\propto L^d$.

Geometric argument

- ▶ Banavar *et al.* assume sink density ρ is **uniform**
- ▶ If we allow ρ to vary, then we find

$$V_{\text{blood}} \propto \rho L^{d+1}$$

- ▶ Since $V_{\text{blood}} \propto L^d$, we must have $\rho \propto L^{-1}$.
- ▶ \Rightarrow capillary density must decrease as M increases (observed).

Geometric argument

- ▶
$$N_{\text{sinks}} \propto \rho L^d \propto L^{-1} L^d \propto M^{(d-1)/d}$$
- ▶ so for $d = 3$, we have $\alpha = 2/3$.
- ▶ for $d = 2$, we have $\alpha = 1/2$.
- ▶ Claim: If volume shapes change allometrically, the exponent **decreases**.
- ▶ Claim: Less Efficient networks have **lower** exponents too (b/c they must have lower densities of sinks).
- ▶ We'll work through these claims in detail...

Geometric argument

- ▶ Reminder: we break network up into virtual vessels:

- ▶ Assume flow rate at each sink is independent of system size.
- ▶ Take the cross-sectional area a of virtual vessels to be constant.
- ▶ Minimizing the volume of the network is then equivalent to minimizing the sum of the path lengths from the source to all sinks.

Introduction

Optimal branching

History

Reframing the question

Minimal volume calculation

Blood networks

River networks

Distributed Sources

Facility location

Size-density law

Cartograms

References

Geometric argument

- ▶ Note: we are ignoring issues such as impedance.
- ▶ Changes in impedance (e.g., due to combining of flows) may change material speed **but not overall flow rate**
- ▶ Scaling of material volume must be \propto system volume—it's a 0th order concern.

Geometric argument

- ▶ Consider families of systems that grow allometrically.
- ▶ Family = a basic shape Ω indexed by volume V .

- ▶ Orient shape to have dimensions $L_1 \times L_2 \times \dots \times L_d$
- ▶ In 2-d, $L_1 \propto A^{\gamma_1}$ and $L_2 \propto A^{\gamma_2}$ where $A = \text{area}$.
- ▶ In general, have d lengths which scale as $L_i \propto V^{\gamma_i}$.
- ▶ For above example, width grows faster than height:
 $\gamma_1 > \gamma_2$.

Geometric argument

Some generality:

- ▶ Consider d dimensional spatial regions living in D dimensional ambient spaces. Notation: $\Omega_{d,D}(V)$.
- ▶ River networks: $d = 2$ and $D = 3$
- ▶ Cardiovascular networks: $d = 3$ and $D = 3$
- ▶ **Star-convexity of $\Omega_{d,D}(V)$:** A spatial region is star-convex if from at least one point, all other points in the region can be reached by travelling along straight lines while remaining within the region.
- ▶ Assume source can be located at a point which has direct line of sight to all sources.
- ▶ We can generalize to a much broader class of shapes...

[Introduction](#)[Optimal branching](#)[Murray meets Tokunaga](#)[Single Source](#)[History](#)[Reframing the question](#)[Minimal volume calculation](#)[Blood networks](#)[River networks](#)[Distributed Sources](#)[Facility location](#)[Size-density law](#)[Cartograms](#)[References](#)

- ▶ Reminder of best and worst configurations

- ▶ **Basic idea:** Minimum volume of material in system
 $V_{\text{net}} \propto$ sum of distance from the source to the sinks.
- ▶ See what this means for sink density ρ if sinks do not change their feeding habits with overall size.

Assumptions in detail:

- ▶ Each region $\Omega_{d,D}(V)$ has overall dimensions $L_1 \times L_2 \times \dots \times L_d$.
- ▶ Specifically, $V = cL_1L_2 \dots L_d$ where $c \leq 1$ is a shape factor dependent of Ω .
- ▶ We allow for arbitrary shape scaling:

$$L_i = c_i^{-1} V^{\gamma_i}$$

where $\prod_{i=1}^d c_i = c$ and $\sum_{i=1}^d \gamma_i = 1$.

- ▶ For **isometric** growth, $\gamma_i = 1/d$.
- ▶ For **allometric** growth, we must have at least two of the $\{\gamma_i\}$ being different
- ▶ We choose the L_i so that $\gamma_1 \geq \gamma_2 \geq \dots \geq \gamma_d$

Computing the minimal network volume:

$$\begin{aligned}\min V_{\text{net}} &\propto \int_{\Omega_{d,D}(V)} \rho \|\vec{x}\| d\vec{x} \\ &= \rho \int_{\Omega_{d,D}(V)} (x_1^2 + x_2^2 + \dots + x_d^2)^{1/2} d\vec{x}\end{aligned}$$

- ▶ Substituting $x_i = L_i u_i$, we have

$$\begin{aligned}\min V_{\text{net}} &\propto \rho L_1 \cdots L_d \int_{\Omega_{d,D}(c)} (L_1^2 u_1^2 + \dots + L_d^2 u_d^2)^{1/2} d\vec{u} \\ &\propto \rho V \int_{\Omega_{d,D}(c)} (L_1^2 u_1^2 + L_2^2 u_2^2 + \dots + L_d^2 u_d^2)^{1/2} d\vec{u}\end{aligned}$$

where we have rescaled to a volume of size $c < 1$
where c is the shape factor.

Computing the minimal network volume:

- ▶ We are here:

$$\min V_{\text{net}} \propto \rho V \int_{\Omega_{d,D}(c)} (L_1^2 u_1^2 + L_2^2 u_2^2 + \dots + L_d^2 u_d^2)^{1/2} d\vec{u}$$

- ▶ **Observe** that the integrand will be dominated by the L_i that scale strongest with V .
- ▶ Assume first $k \leq d$ dimensions scale with equal strength, $L_i = c_i^{-1} V^{\gamma^*}$.
- ▶ Plug in scaling for L_i in terms of V and pull V^{γ^*} out to the front.

$$\min V_{\text{net}} \propto \rho V V^{\gamma^*} \int_{\Omega_{d,D}(c)} (c_1^{-2} u_1^2 + \dots + c_k^2 u_k^2 + \dots$$

$$c_{k+1}^{-2} V^{2(\gamma_{k+1}-\gamma^*)} u_{k+1}^2 + \dots + c_d^{-2} V^{2(\gamma_d-\gamma^*)} u_d^2)^{1/2} d\vec{u}$$

Computing the minimal network volume:

- Where we are now:

$$\min V_{\text{net}} \propto \rho V^{1+\gamma^*} \int_{\Omega_{d,D}(c)} (c_1^{-2} u_1^2 + \dots + c_k^{-2} u_k^2 + \dots \\ c_{k+1}^2 V^{2(\gamma_{k+1}-\gamma^*)} u_{k+1}^2 + \dots + c_d^2 V^{2(\gamma_d-\gamma^*)} u_d^2)^{1/2} d\vec{u}$$

- Now allow $V \rightarrow \infty$ and see that part of integrand vanishes:

$$\min V_{\text{net}} \rightarrow \rho V^{1+\gamma^*} \int_{\Omega_{d,D}(c)} (c_1^2 u_1^2 + \dots + c_k^2 u_k^2)^{1/2} d\vec{u} \\ \propto \rho V^{1+\gamma^*}$$

since integral is now nice and friendly and small.

River networks

Distributed Sources

Facility location

Size-density law

Cartograms

References

Geometric argument

- ▶ Our general result:

$$\min V_{\text{net}} \propto \rho V^{1+\gamma_*}$$

- ▶ For scaling is **isometric**, we have $\gamma_* = \gamma_{\text{iso}} = 1/d$ and all the L_j scale as $V^{1/d}$:

$$\min V_{\text{net/iso}} \propto \rho V^{1+1/d} = \rho V^{(d+1)/d}$$

- ▶ If scaling is **allometric**, we have

$$\gamma_* = \gamma_{\text{allo}} = \max_j \gamma_j > 1/d \text{ and}$$

$$\min V_{\text{net/allo}} \propto \rho V^{1+\gamma_{\text{allo}}}$$

- ▶ We see that isometrically scaling volumes **require less network volume** than allometrically scaling volumes:

$$\frac{\min V_{\text{net/iso}}}{\min V_{\text{net/allo}}} \rightarrow 0 \text{ as } V \rightarrow \infty$$

Some data on metabolic rates

- ▶ Heusner's data (1991) [5]
- ▶ 391 Mammals
- ▶ blue line: 2/3
- ▶ red line: 3/4.
- ▶ $B = P =$ power

Geometric argument

Interesting result from quantum mechanics:

- ▶ Homeothermic organisms need to keep their temperature static
- ▶ A good amount of heat loss is through infra-red radiation (when resting)
- ▶ For mammals with $M \leq 10$ kg:
 $P = 2.57 \times 10^5 M^{2/3}$ erg/sec.
- ▶ Stefan-Boltzmann's law (⊕): $\frac{dE}{dt} = \sigma \varepsilon S T^4$
 where T is absolute temperature, S is surface area, ε = emissivity < 1 and σ depends on Planck's constant, speed of light, π^5 , these sorts of things.
- ▶ Rough estimates of these constants give

$$P \simeq 10^5 M^{2/3} \text{ erg/sec.}$$

Not bad...

Geometric argument

- ▶ River networks can be seen as collection networks.
- ▶ Many sources and one sink.
- ▶ For river networks, we know ρ is constant so

$$V_{\text{net}} \propto \rho V^{(d+1)/d} = \text{constant} \times V^{3/2}$$

- ▶ **Hmmm:** now network volume is growing faster than basin 'volume' (really area).
- ▶ **It's all okay:**
Landscapes are 2-d surfaces living in 3-d.
- ▶ $D = 3$ and $d = 2$.
- ▶ Streams can grow not just in width but in depth...

- ▶ Volume of water in river network can be calculated by adding up basin areas
- ▶ (Discreteness of data means summing instead of integrating)
- ▶ Each site on discrete lattice is a source.
- ▶ Imagine a steady flow from each source to outlet.
- ▶ Flows sum in such a way that

$$V_{\text{net}} = \sum_{\text{all pixels}} a_{\text{pixel } i}$$

Geometric argument

- ▶ Banavar et al.'s approach^[1] is okay because ρ really is constant.
- ▶ **The irony:** shows optimal basins are isometric
- ▶ Optimal Hack's law: $a \sim \ell^h$ with $h = 1/2$
- ▶ (Zzzzz)

From Banavar et al. (1999)^[1]

Geometric argument: evidence

Montgomery and Dietrich [7]

- ▶
- ▶ Composite data set: includes everything from unchanneled valleys up to world's largest rivers.
- ▶ Estimated fit:

$$L \simeq 1.78a^{0.49}$$

- ▶ N.b., data is a mixture of basin and main stream lengths.

Optimal source allocation

- ▶ Consider a region of area A and population P with a single functional center that everyone needs to access every day.
- ▶ Build up a general cost function based on time expended to **access and maintain center**.
- ▶ Write **average travel distance** to center is \bar{d} and assume **average speed of travel** is \bar{v} .
- ▶ Note that average travel distance will be on the length scale of the region which is $A^{1/2}$
- ▶ Average time expended per person in accessing facility is therefore

$$\bar{d}/\bar{v} = cA^{1/2}/\bar{v}$$

where c is an unimportant shape factor.

Optimal source allocation

- ▶ Next assume facility requires regular maintenance (person-hours per day)
- ▶ Call this quantity τ
- ▶ If burden of maintenance is shared then average cost per person is τ/P .
- ▶ Replace P by ρA where ρ is density.
- ▶ Total average time cost per person:

$$T = \bar{d}/\bar{v} + \tau/(\rho A) = gA^{1/2}/\bar{v} + \tau/(\rho A).$$

- ▶ Now Minimize with respect to A ...

Optimal source allocation

- ▶ Differentiating...

$$\begin{aligned}\frac{\partial T}{\partial A} &= \frac{\partial}{\partial A} \left(cA^{1/2}/\bar{v} + \tau/(\rho A) \right) \\ &= c/(2\bar{v}A^{1/2}) - \tau/(\rho A^2) = 0\end{aligned}$$

- ▶ Rearrange:

$$A = (2\bar{v}\tau/c\rho)^{2/3} \propto \rho^{-2/3}$$

- ▶ # facilities per unit area \propto

$$A^{-1} \propto \rho^{2/3}$$

- ▶ Groovy...

An issue:

- ▶ Maintenance (τ) is assumed to be **independent** of population and area (P and A)

Diffusion-based cartograms:

- ▶ Idea of cartograms is to **distort areas** to more accurately represent some local density ρ (e.g. population).
- ▶ Many methods put forward—typically involve some kind of physical analogy to **spreading or repulsion**.
- ▶ Algorithm due to Gastner and Newman (2004) [3] is based on **standard diffusion**:

$$\nabla^2 \rho - \frac{\partial \rho}{\partial t} = 0.$$

- ▶ Allow density to diffuse and trace the movement of individual elements and boundaries.
- ▶ Diffusion is constrained by boundary condition of surrounding area having density $\bar{\rho}$.

Deriving the optimal source distribution:

- ▶ **Basic idea:** Minimize the average distance from a random individual to the nearest facility. [3]
- ▶ Assume given a fixed population density ρ defined on a spatial region Ω .
- ▶ Formally, we want to find the locations of n sources $\{\vec{x}_1, \dots, \vec{x}_n\}$ that minimizes the **cost function**

$$F(\{\vec{x}_1, \dots, \vec{x}_n\}) = \int_{\Omega} \rho(\vec{x}) \min_i \|\vec{x} - \vec{x}_i\| d\vec{x}.$$

- ▶ Also known as the p-median problem.
- ▶ Not easy... in fact this one is an NP-hard problem. [3]

Approximations:

- ▶ For a given set of source placements $\{\vec{x}_1, \dots, \vec{x}_n\}$, the region Ω is divided up into Voronoi cells (田), one per source.
- ▶ Define $A(\vec{x})$ as the **area** of the Voronoi cell containing \vec{x} .
- ▶ As per Stephan's calculation, estimate typical distance from \vec{x} to the nearest source (say i) as

$$c_i A(\vec{x})^{1/2}$$

where c_i is a shape factor for the i th Voronoi cell.

- ▶ Approximate c_i as a constant c .

Carrying on:

- ▶ The cost function is now

$$F = c \int_{\Omega} \rho(\vec{x}) A(\vec{x})^{1/2} d\vec{x}.$$

- ▶ We also have that the **constraint** that Voronoi cells divide up the overall area of Ω : $\sum_{i=1}^n A(\vec{x}_i) = A_{\Omega}$.
- ▶ Sneakily turn this into an integral constraint:

$$\int_{\Omega} \frac{d\vec{x}}{A(\vec{x})} = n.$$

- ▶ Within each cell, $A(\vec{x})$ is constant.
- ▶ So... integral over each of the n cells equals 1.

Size-density law

Now a Lagrange multiplier story:

- ▶ By varying $\{\vec{x}_1, \dots, \vec{x}_n\}$, minimize

$$G(A) = c \int_{\Omega} \rho(\vec{x}) A(\vec{x})^{1/2} d\vec{x} - \lambda \left(n - \int_{\Omega} [A(\vec{x})]^{-1} d\vec{x} \right)$$

- ▶ Next compute $\delta G / \delta A$, the functional derivative (\boxplus) of the functional $G(A)$.
- ▶ This gives

$$\int_{\Omega} \left[\frac{-c}{2} \rho(\vec{x}) A(\vec{x})^{-1/2} + \lambda [A(\vec{x})]^{-2} \right] d\vec{x}$$

- ▶ Setting the integrand to be zilch, we have:

$$\rho(\vec{x}) = 2\lambda c^{-1} A(\vec{x})^{-3/2}.$$

Size-density law

Now a Lagrange multiplier story:

- ▶ Rearranging, we have

$$A(\vec{x}) = (2\lambda c^{-1})^{2/3} \rho^{-2/3}.$$

- ▶ Finally, we identify $1/A(\vec{x})$ as $D(\vec{x})$, an approximation of the local source density.
- ▶ Substituting $D = 1/A$, we have

$$D(\vec{x}) = \left(\frac{c}{2\lambda} \rho \right)^{2/3}.$$

- ▶ Normalizing (or solving for λ):

$$D(\vec{x}) = n \frac{[\rho(\vec{x})]^{2/3}}{\int_{\Omega} [\rho(\vec{x})]^{2/3} d\vec{x}} \propto [\rho(\vec{x})]^{2/3}.$$

One more thing:

- ▶ How do we supply these facilities?
- ▶ How do we best redistribute mail? People?
- ▶ How do we get beer to the pubs?
- ▶ Gaster and Newman model: cost is a function of basic maintenance and travel time:

$$C_{\text{maint}} + \gamma C_{\text{travel}}.$$

- ▶ Travel time is more complicated: Take 'distance' between nodes to be a composite of shortest path distance ℓ_{ij} and number of legs to journey:

$$(1 - \delta)\ell_{ij} + \delta(\#\text{hops}).$$

- ▶ When $\delta = 1$, only number of hops matters.
