## Mandelbrot:

“We shall restate in detail our 1959 objections to Simon’s 1955 model for the Pareto-Yule-Zipf distribution. **Our objections are valid** quite irrespectively of the sign of  $p-1$ , so that **most of Simon’s (1960) reply was irrelevant.**”

## Simon:

“Dr. Mandelbrot has proposed a new set of objections to my 1955 models of the Yule distribution. **Like his earlier objections, these are invalid.**”

## Plankton:

“You can’t do this to me, **I WENT TO COLLEGE!**” “You weak minded fool!”  
“That’s it Mister! You just lost your brain privileges,” etc.

## Mandelbrot's Assumptions

- ▶ Language contains  $n$  words:  $w_1, w_2, \dots, w_n$ .
- ▶  $i$ th word appears with probability  $p_i$
- ▶ Words appear randomly according to this distribution (obviously not true...)
- ▶ Words = composition of letters is important
- ▶ Alphabet contains  $m$  letters
- ▶ Words are ordered by length (shortest first)

## Word Cost

- ▶ **Length of word** (plus a space)
- ▶ Word length was irrelevant for Simon's method

## Objection

- ▶ Real words don't use all letter sequences

## Objections to Objection

- ▶ Maybe real words roughly follow this pattern (?)
- ▶ Words can be encoded this way
- ▶ Na na na-na naaaaa...

## Binary alphabet plus a space symbol

$i$	1	2	3	4	5	6	7	8
word	1	10	11	100	101	110	111	1000
length	1	2	2	3	3	3	3	4
$1 + \ln_2 i$	1	2	2.58	3	3.32	3.58	3.81	4

- ▶ Word length of  $2^k$ th word:  $= k + 1 = 1 + \log_2 2^k$
- ▶ Word length of  $i$ th word  $\simeq 1 + \log_2 i$
- ▶ For an alphabet with  $m$  letters,  
word length of  $i$ th word  $\simeq 1 + \log_m i$ .

## Total Cost $C$

- ▶ Cost of the  $i$ th word:  $C_i \simeq 1 + \log_m i$
- ▶ Cost of the  $i$ th word plus space:  $C_i \simeq 1 + \log_m(i + 1)$
- ▶ Subtract fixed cost:  $C'_i = C_i - 1 \simeq \log_m(i + 1)$
- ▶ Simplify base of logarithm:

$$C'_i \simeq \log_m(i + 1) = \frac{\log_e(i + 1)}{\log_e m} \propto \ln(i + 1)$$

- ▶ Total Cost:

$$C \sim \sum_{i=1}^n p_i C'_i \propto \sum_{i=1}^n p_i \ln(i + 1)$$

## Information Measure

- ▶ Use Shannon's Entropy (or Uncertainty):

$$H = - \sum_{i=1}^n p_i \log_2 p_i$$

- ▶ (allegedly) von Neumann suggested 'entropy'...
- ▶ Proportional to average number of bits needed to encode each 'word' based on frequency of occurrence
- ▶  $-\log_2 p_i = \log_2 1/p_i =$  minimum number of bits needed to distinguish event  $i$  from all others
- ▶ If  $p_i = 1/2$ , **need only 1 bit** ( $\log_2 1/p_i = 1$ )
- ▶ If  $p_i = 1/64$ , **need 6 bits** ( $\log_2 1/p_i = 6$ )

# Zipfarama via Optimization

Differentiate with respect to  $p_j$ :

$$\frac{\partial \Psi}{\partial p_j} = \frac{\partial(C/H)}{\partial p_j} + \frac{\partial}{\partial p_j} \lambda \left( \sum_{i=1}^n p_i - 1 \right) (= 0)$$

$$= \frac{\frac{\partial C}{\partial p_j} H - C \frac{\partial H}{\partial p_j}}{H^2} + \lambda$$

$$= \frac{\frac{\partial}{\partial p_j} (\sum_{i=1}^n p_i \ln(i+1)) H - C \frac{\partial}{\partial p_j} (-g \sum_{i=1}^n p_i \ln p_i)}{H^2} + \lambda$$

$$\frac{H \ln(j+1) + gC(\ln p_j + p_j/p_j \cancel{p_j/p_j} 1)}{H^2} + \lambda = 0$$

## Finding the exponent

- ▶ Expressions for  $H$  and  $C$  are implicit functions.
- ▶ Not terribly obvious what the exponent will be.
- ▶ **Let's find out...**
- ▶ First: Determine  $\lambda$
- ▶ Sneakiness: Substitute form for  $p_j$  into  $H$
- ▶ Find  $\lambda = -gC/H^2$   
Our form for  $p_j$  reduces:

$$p_j = e^{-1-\lambda H^2/gC} (j+1)^{-H/gC}$$
$$= e^{-1+1} (j+1)^{-H/gC} = (j+1)^{-H/gC}$$

## Finding the exponent

- ▶ Now use the normalization constraint:

$$1 = \sum_{j=1}^n p_j = \sum_{j=1}^n (j+1)^{-H/gC} = \sum_{j=1}^n (j+1)^{-\alpha}$$

- ▶ As  $n \rightarrow \infty$ , we end up with  $\zeta(H/gC) = 2$  where  $\zeta$  is the Riemann Zeta Function
- ▶ Gives  $\alpha \simeq 1.73$  ( $> 1$ , too high)
- ▶ If cost function **changes** ( $j+1 \rightarrow j+a$ ) then exponent is tunable
- ▶ Increase  $a$ , decrease  $\alpha$

# Economics, Schmeconomics

## Greenspan continues:

“The trouble is that we can’t figure that out. I’ve been in the forecasting business for 50 years. I’m no better than I ever was, and nobody else is. Forecasting 50 years ago was as good or as bad as it is today. And the reason is that human nature hasn’t changed. We can’t improve ourselves.”

## Jon Stewart:

“You just bummed the @\*!# out of me.”

James K. Galbraith:

- ▶ But there are at least 15,000 professional economists in this country, and you're saying only two or three of them foresaw the mortgage crisis? **Ten or 12 would be closer than two or three.**
- ▶ What does that say about the field of economics, which claims to be a science? **It's an enormous blot on the reputation of the profession.** There are thousands of economists. Most of them teach. **And most of them teach a theoretical framework that has been shown to be fundamentally useless.**

## SOC = Self-Organized Criticality

- ▶ Idea: natural dissipative systems exist at 'critical states'
- ▶ Analogy: Ising model with temperature somehow self-tuning
- ▶ Power-law distributions of sizes and frequencies arise 'for free'
- ▶ Introduced in 1987 by Bak, Tang, and Weisenfeld [3, 2, 9]:  
"Self-organized criticality - an explanation of  $1/f$  noise"
- ▶ **Problem:** Critical state is a very specific point
- ▶ Self-tuning not always possible
- ▶ Much criticism and arguing...

## Aside:

- ▶ Power law distributions often have an exponential cutoff

$$P(x) \sim x^{-\gamma} \exp^{-x/x_c}$$

- ▶ where  $x_c$  is the approximate cutoff scale.

## References

- ▶ Scale-free networks are thus **robust to random failures** yet **fragile to targeted ones**.
- ▶ All very reasonable: **Hubs** are a big deal.
- ▶ **But:** next issue is whether hubs are vulnerable or not.
- ▶ Representing all webpages as the same size node is obviously a stretch (e.g., google vs. a random person's webpage)
- ▶ Most connected nodes are either:
  1. Physically larger nodes that may be harder to 'target'
  2. or subnetworks of smaller, normal-sized nodes.
- ▶ Need to explore cost of various targeting schemes.
