## We need to understand influence

- ▶ Who influences whom? Very hard to measure...
- ▶ What kinds of influence response functions are there?
- ▶ Are some individuals super influencers? Highly popularized by Gladwell [8] as 'connectors'
- ▶ The infectious idea of opinion leaders (Katz and Lazarsfeld) [12]

### Why do things spread?

- ▶ Because of system level properties?
- ▶ Or properties of special individuals?
- ▶ Is the match that lights the fire important?
- ▶ Yes. But only because we are narrative-making machines...
- ▶ We like to think things happened for reasons...
- ▶ System/group properties harder to understand
- ▶ Always good to examine what is said before and after the fact...

## Getting others to do things for you

A very good book: **'Influence'** by Robert Cialdini <sup>[7]</sup>

### Six modes of influence

1. **Reciprocation**: *The Old Give and Take... and Take*
2. **Commitment and Consistency**: *Hobgoblins of the Mind*
3. **Social Proof**: *Truths Are Us*
4. **Liking**: *The Friendly Thief*
5. **Authority**: *Directed Deference*
6. **Scarcity**: *The Rule of the Few*

Social Contagion

# Social contagion models

## Thresholds

- ▶ Basic idea: individuals adopt a behavior when a **certain fraction of others** have adopted
- ▶ 'Others' may be everyone in a population, an individual's close friends, any reference group.
- ▶ Response can be probabilistic or deterministic.
- ▶ Individual thresholds can vary
- ▶ Assumption: order of others' adoption does not matter... **(unrealistic)**.
- ▶ Assumption: level of influence per person is uniform **(unrealistic)**.

Social Contagion

Social Contagion  
Models

Granovetter's model  
Network version  
Groups  
Chaos

References

Frame 23/86

# Social Contagion

## Some possible origins of thresholds:

- ▶ **Desire to coordinate**, to conform.
- ▶ **Lack of information**: impute the worth of a good or behavior based on degree of adoption (social proof)
- ▶ Economics: **Network effects** or **network externalities**
- ▶ Externalities = Effects on others not directly involved in a transaction
- ▶ Examples: telephones, fax machine, Facebook, operating systems
- ▶ An individual's utility increases with the adoption level among peers and the population in general

# Social Contagion

## Granovetter's Threshold model—definitions

- ▶  $\phi^*$  = threshold of an individual.
- ▶  $f(\phi_*)$  = distribution of thresholds in a population.
- ▶  $F(\phi_*)$  = cumulative distribution =  $\int_{\phi'_*=0}^{\phi_*} f(\phi'_*)d\phi'_*$
- ▶  $\phi_t$  = fraction of people 'rioting' at time step  $t$ .

Social Contagion

Social Contagion  
Models

Granovetter's model  
Network version  
Groups  
Chaos

References

Frame 26/86

# Threshold models

- ▶ Example threshold influence response functions: **deterministic** and **stochastic**
- ▶  $\phi$  = fraction of contacts 'on' (e.g., rioting)
- ▶ Two states: S and I.

# Threshold models

- ▶ At time  $t + 1$ , fraction rioting = fraction with  $\phi_* \leq \phi_t$ .

$$\phi_{t+1} = \int_0^{\phi_t} f(\phi_*) d\phi_* = F(\phi_*)|_0^{\phi_t} = F(\phi_t)$$

- ▶  $\Rightarrow$  Iterative maps of the unit interval  $[0, 1]$ .

# Threshold models

Action based on perceived behavior of others.

- ▶ Two states: S and I.
- ▶  $\phi$  = fraction of contacts 'on' (e.g., rioting)
- ▶ Discrete time update (strong assumption!)
- ▶ This is a **Critical mass model**

# Threshold models

- ▶ Another example of critical mass model...

## Threshold models

- ▶ Example of single stable state model

## Threshold models

### Implications for collective action theory:

1. Collective uniformity  $\not\Rightarrow$  individual uniformity
2. Small individual changes  $\Rightarrow$  large global changes

## Threshold models

### Chaotic behavior possible [11, 10]

- ▶ Period doubling arises as map amplitude  $r$  is increased.
- ▶ Synchronous update assumption is crucial

## Threshold model on a network

Many years after Granovetter and Soong's work:

**"A simple model of global cascades on random networks"**

D. J. Watts. Proc. Natl. Acad. Sci., 2002 [19]

- ▶ Mean field model  $\rightarrow$  network model
- ▶ Individuals now have a limited view of the world

## Threshold model on a network

- ▶ Interactions between individuals now represented by a network
- ▶ Network is **sparse**
- ▶ Individual  $i$  has  $k_i$  contacts
- ▶ Influence on each link is **reciprocal** and of **unit weight**
- ▶ Each individual  $i$  has a fixed threshold  $\phi_i$
- ▶ Individuals repeatedly poll contacts on network
- ▶ Synchronous, discrete time updating
- ▶ Individual  $i$  becomes active when fraction of active contacts  $a_i \geq \phi_i k_i$
- ▶ Individuals remain active when switched (no recovery = SI model)

## Snowballing

### The Cascade Condition:

If one individual is initially activated, what is the probability that an activation will spread over a network?

What features of a network determine whether a cascade will occur or not?

Social Contagion

Social Contagion Models

- Background
- Granovetter's model
- Network version**
- Groups
- Chaos

References

Frame 38/86

## Snowballing

### First study random networks:

- ▶ Start with  $N$  nodes with a degree distribution  $p_k$
- ▶ Nodes are randomly connected (carefully so)
- ▶ Aim: Figure out when activation will propagate
- ▶ Determine a **cascade condition**

Social Contagion

Social Contagion Models

- Background
- Granovetter's model
- Network version**
- Groups
- Chaos

References

Frame 39/86

# Snowballing

## Follow active links

- ▶ An active link is a link connected to an activated node.
- ▶ If an infected link leads to **at least 1 more infected link**, then **activation spreads**.
- ▶ We need to understand which nodes can be activated when only one of their neighbors becomes active.

Social Contagion

Social Contagion Models

- Background
- Granovetter's model
- Network version
- Groups
- Chaos

References

Frame 40/86

# The most gullible

## Vulnerables:

- ▶ We call individuals who can be activated by just one contact being active **vulnerables**
- ▶ The vulnerability condition for node  $i$ :

$$1/k_i \geq \phi_i$$

- ▶ Which means # contacts  $k_i \leq \lfloor 1/\phi_i \rfloor$
- ▶ For global cascades on random networks, must have a **global cluster of vulnerables**<sup>[19]</sup>
- ▶ **Cluster of vulnerables = critical mass**
- ▶ Network story: 1 node → critical mass → everyone.

Social Contagion

Social Contagion Models

- Background
- Granovetter's model
- Network version
- Groups
- Chaos

References

Frame 41/86

# Cascade condition

## Back to following a link:

- ▶ Link from leads to a node with probability  $\propto kP_k$ .
- ▶ Follows from links being random + having  $k$  chances to connect to a node with degree  $k$ .
- ▶ Normalization:

$$\sum_{k=0}^{\infty} kP_k = \langle k \rangle = z$$

- ▶ So

$$P(\text{linked node has degree } k) = \frac{kP_k}{\langle k \rangle}$$

Social Contagion

Social Contagion Models

- Background
- Granovetter's model
- Network version
- Groups
- Chaos

References

Frame 42/86

# Cascade condition

## Next: Vulnerability of linked node

- ▶ Linked node is **vulnerable** with probability

$$\beta_k = \int_{\phi'_*=0}^{1/k} f(\phi'_*) d\phi'_*$$

- ▶ If linked node is **vulnerable**, it produces  **$k - 1$  new** outgoing active links
- ▶ If linked node is **not vulnerable**, it produces **no** active links.

Social Contagion

Social Contagion Models

- Background
- Granovetter's model
- Network version
- Groups
- Chaos

References

Frame 43/86

# Cascade condition

## Putting things together:

- ▶ Expected number of active edges produced by an active edge =

$$\sum_{k=1}^{\infty} \underbrace{(k-1)\beta_k \frac{kP_k}{z}}_{\text{success}} + \underbrace{0(1-\beta_k) \frac{kP_k}{z}}_{\text{failure}}$$

$$= \sum_{k=1}^{\infty} (k-1)k\beta_k P_k / z$$

# Cascade condition

So... for random networks with fixed degree distributions, cascades take off when:

$$\sum_{k=1}^{\infty} k(k-1)\beta_k P_k / z \geq 1.$$

- ▶  $\beta_k$  = probability a degree  $k$  node is vulnerable.
- ▶  $P_k$  = probability a node has degree  $k$ .

# Cascade condition

## Two special cases:

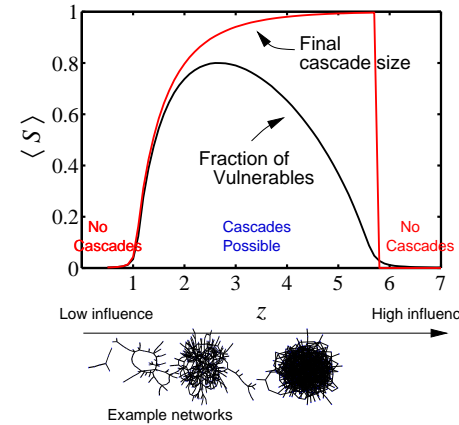

- ▶ (1) Simple disease-like spreading succeeds:  $\beta_k = \beta$

$$\beta \sum_{k=1}^{\infty} k(k-1)P_k / z \geq 1.$$

- ▶ (2) Giant component exists:  $\beta = 1$

$$\sum_{k=1}^{\infty} k(k-1)P_k / z \geq 1.$$

# Cascades on random networks

- ▶ Cascades occur only if size of max vulnerable cluster  $> 0$ .
- ▶ System may be 'robust-yet-fragile'.
- ▶ 'Ignorance' facilitates spreading.

## Cascade window for random networks

- ▶ 'Cascade window' widens as threshold  $\phi$  decreases.
- ▶ Lower thresholds enable spreading.

## Cascade window—summary

For our simple model of a uniform threshold:

1. **Low  $\langle k \rangle$ :** No cascades in poorly connected networks. No global clusters of any kind.
2. **High  $\langle k \rangle$ :** Giant component exists but not enough vulnerables.
3. **Intermediate  $\langle k \rangle$ :** Global cluster of vulnerables exists. Cascades are possible in "Cascade window."

Frame 51/86

## Early adopters—degree distributions

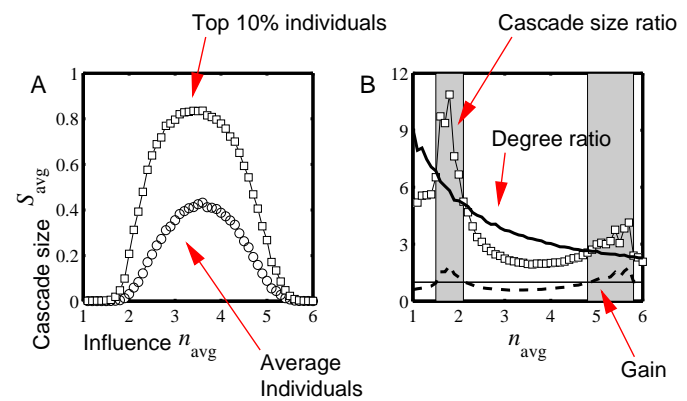

$P_{k,t}$  versus  $k$

## The multiplier effect:

- ▶ Fairly uniform levels of individual influence.
- ▶ Multiplier effect is mostly below 1.

## The multiplier effect:

- ▶ Skewed influence distribution example.

## Special subnetworks can act as triggers

- ▶  $\phi = 1/3$  for all nodes

# The power of groups...

“A few harmless flakes working together can unleash an avalanche of destruction.”

despair.com

# Extensions

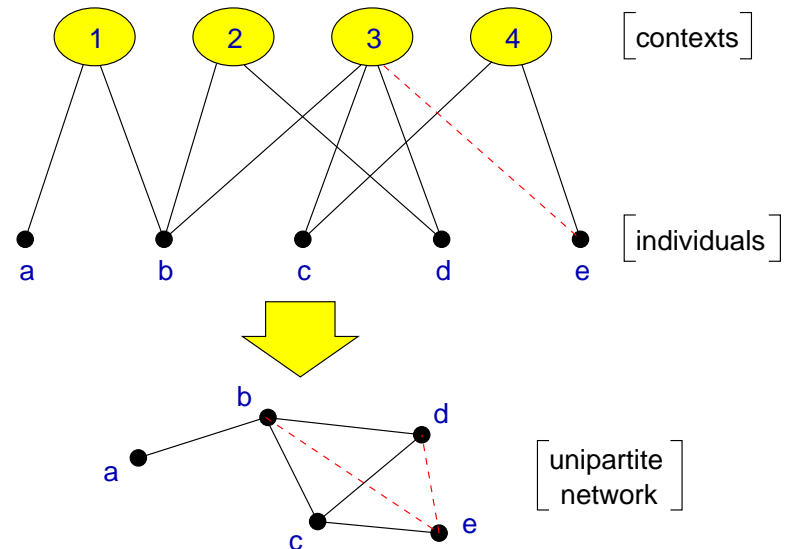

- ▶ Assumption of sparse interactions is good
- ▶ Degree distribution is (generally) key to a network's function
- ▶ Still, random networks don't represent all networks
- ▶ Major element missing: **group structure**

# Group structure—Ramified random networks

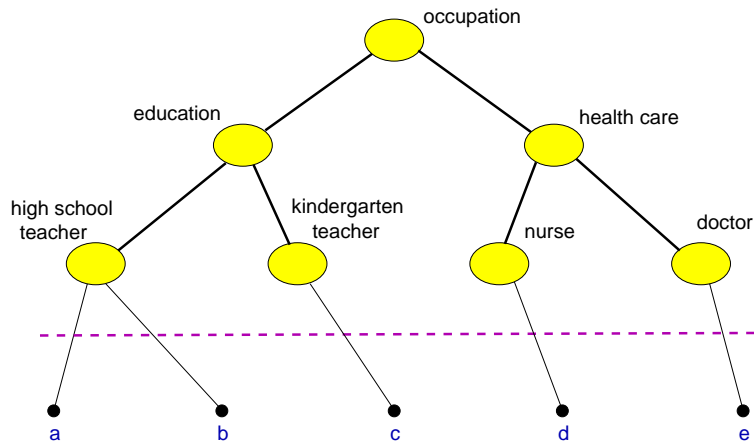

$p$  = intergroup connection probability  
 $q$  = intragroup connection probability.

# Bipartite networks

## Context distance

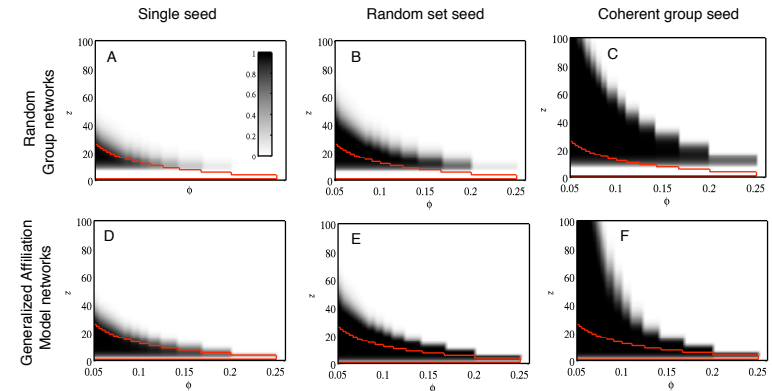

## Generalized affiliation model

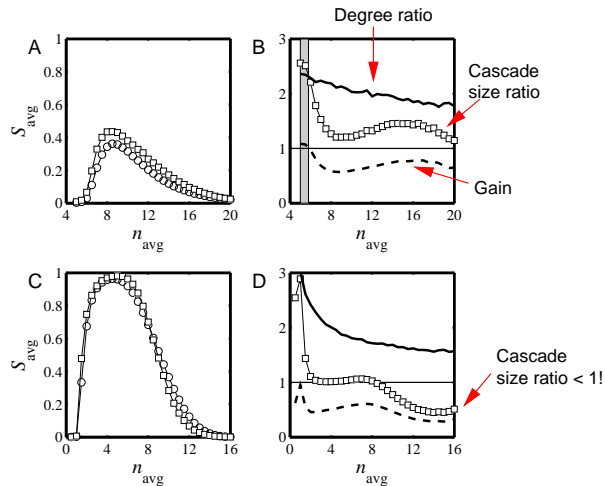

## Generalized affiliation model networks with triadic closure

- ▶ Connect nodes with probability  $\propto \exp^{-\alpha d}$  where
  - $\alpha$  = homophily parameter and
  - $d$  = distance between nodes (height of lowest common ancestor)
- ▶  $\tau_1$  = intergroup probability of friend-of-friend connection
- ▶  $\tau_2$  = intragroup probability of friend-of-friend connection

## Cascade windows for group-based networks

## Multiplier effect for group-based networks:

- ▶ Multiplier almost always below 1.

## Assortativity in group-based networks

- ▶ The most connected nodes aren't always the most 'influential.'
- ▶ **Degree assortativity** is the reason.

## Social contagion

### Summary

- ▶ **'Influential vulnerables'** are key to spread.
- ▶ Early adopters are mostly vulnerables.
- ▶ Vulnerable nodes important but not necessary.
- ▶ Groups may greatly facilitate spread.
- ▶ Seems that cascade condition is a global one.
- ▶ Most extreme/unexpected cascades occur in highly connected networks
- ▶ 'Influentials' are posterior constructs.
- ▶ Many potential influentials exist.

## Social contagion

### Implications

- ▶ Focus on **the influential vulnerables**.
- ▶ Create entities that can be transmitted successfully through many individuals rather than broadcast from one 'influential.'
- ▶ Only **simple ideas** can spread by word-of-mouth. (Idea of opinion leaders spreads well...)
- ▶ Want enough individuals who will adopt and display.
- ▶ Displaying can be **passive** = free (yo-yo's, fashion), or **active** = harder to achieve (political messages).
- ▶ Entities can be novel or designed to combine with others, e.g. block another one.

# Chaotic contagion:

- ▶ What if individual response functions are not monotonic?
- ▶ Consider a simple deterministic version:

- ▶ Node  $i$  has an 'activation threshold'  $\phi_{i,1}$  ... and a 'de-activation threshold'  $\phi_{i,2}$
- ▶ Nodes like to imitate but only up to a limit—they don't want to be like everyone else.

Frame 73/86

# Chaotic behavior

Take  $r = 2$  case:

- ▶ What happens if nodes have limited information?
- ▶ As before, allow interactions to take place on a sparse random network.
- ▶ Vary average degree  $z = \langle k \rangle$ , a measure of information

# Invariant densities—stochastic response functions

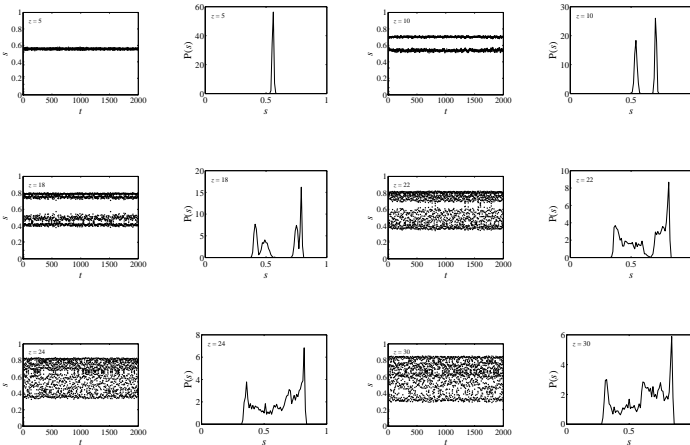

activation time series

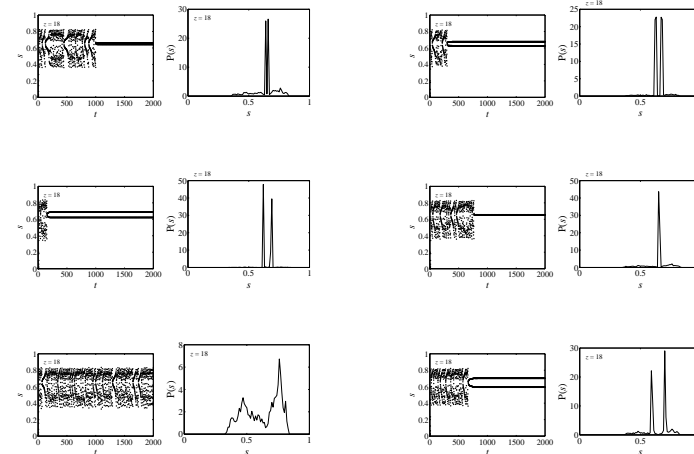

activation density

# Invariant densities—stochastic response functions

# Invariant densities—deterministic response functions for one specific network with $\langle k \rangle = 18$

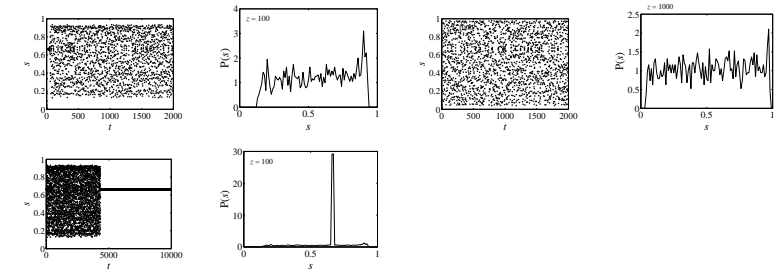

# Invariant densities—stochastic response functions

Trying out higher values of  $\langle k \rangle \dots$

# Invariant densities—deterministic response functions

Trying out higher values of  $\langle k \rangle \dots$

# Connectivity leads to chaos:

Stochastic response functions:

# Chaotic behavior in coupled systems

Coupled maps are well explored (Kaneko/Kuramoto):

$$x_{i,n+1} = f(x_{i,n}) + \sum_{j \in \mathcal{N}_i} \delta_{i,j} f(x_{j,n})$$

- ▶  $\mathcal{N}_i$  = neighborhood of node  $i$
- 1. Node states are **continuous**
- 2. Increase  $\delta$  and neighborhood size  $|\mathcal{N}|$   
⇒ **synchronization**

But for contagion model:

- 1. Node states are **binary**
- 2. **Asynchrony remains** as connectivity increases

## Bifurcation diagram: Asynchronous updating
