Can Horton and Tokunaga be happy?

Horton and Tokunaga seem different:

- ▶ In terms of network architecture, Horton's laws appear to contain less detailed information than Tokunaga's law.
- ▶ Oddly, Horton's laws have **four** parameters and Tokunaga has **two** parameters.
- ▶ R_n , R_a , R_ℓ , and R_s **versus** T_1 and R_T . One simple redundancy: $R_\ell = R_s$.
Insert question from assignment 1 (田)
- ▶ To make a connection, clearest approach is to start with Tokunaga's law...
- ▶ Known result: Tokunaga → Horton ^[18, 19, 20, 9, 2]

Let us make them happy

We need one more ingredient:

Space-fillingness

- ▶ A network is **space-filling** if the average distance between adjacent streams is roughly constant.
- ▶ Reasonable for river and cardiovascular networks
- ▶ For river networks:
Drainage density ρ_{dd} = inverse of typical distance between channels in a landscape.
- ▶ In terms of basin characteristics:

$$\rho_{dd} \simeq \frac{\sum \text{stream segment lengths}}{\text{basin area}} = \frac{\sum_{w=1}^{\Omega} n_w \bar{s}_w}{a_{\Omega}}$$

More with the happy-making thing

Start with Tokunaga's law: $T_k = T_1 R_T^{k-1}$

- ▶ Start looking for Horton's stream number law: $n_\omega/n_{\omega+1} = R_n$.
- ▶ Estimate n_ω , the number of streams of order ω in terms of other $n_{\omega'}, \omega' > \omega$.
- ▶ Observe that each stream of order ω terminates by either:

1. Running into another stream of order ω and generating a stream of order $\omega + 1$...
 - ▶ $2n_{\omega+1}$ streams of order ω do this
2. Running into and being absorbed by a stream of higher order $\omega' > \omega$...
 - ▶ $n'_{\omega'} T_{\omega'-\omega}$ streams of order ω do this

Frame 5/74

More with the happy-making thing

Putting things together:

$$n_\omega = \underbrace{2n_{\omega+1}}_{\text{generation}} + \sum_{\omega'=\omega+1}^{\Omega} \underbrace{T_{\omega'-\omega} n_{\omega'}}_{\text{absorption}}$$

- ▶ Use Tokunaga's law and manipulate expression to create R_n 's.
- ▶ Insert question from assignment 1 (田)
- ▶ Solution:

$$R_n = \frac{(2 + R_T + T_1) \pm \sqrt{(2 + R_T + T_1)^2 - 8R_T}}{2}$$

(The larger value is the one we want.)

Frame 6/74

Finding other Horton ratios

Connect Tokunaga to R_s

- ▶ Now use uniform drainage density ρ_{dd} .
- ▶ Assume side streams are roughly separated by distance $1/\rho_{dd}$.
- ▶ For an order ω **stream segment**, expected length is

$$\bar{s}_\omega \simeq \rho_{dd}^{-1} \left(1 + \sum_{k=1}^{\omega-1} T_k \right)$$

- ▶ Substitute in Tokunaga's law $T_k = T_1 R_T^{k-1}$:

$$\bar{s}_\omega \simeq \rho_{dd}^{-1} \left(1 + T_1 \sum_{k=1}^{\omega-1} R_T^{k-1} \right) \propto R_T^\omega$$

Branching Networks II

Horton ↔ Tokunaga

Reducing Horton

Scaling relations

Fluctuations

Models

Nutshell

References

Frame 7/74

Horton and Tokunaga are happy

Altogether then:

$$\Rightarrow \bar{s}_\omega / \bar{s}_{\omega-1} = R_T \Rightarrow R_s = R_T$$

- ▶ Recall $R_\ell = R_s$ so

$$R_\ell = R_T$$

- ▶ And from before:

$$R_n = \frac{(2 + R_T + T_1) + \sqrt{(2 + R_T + T_1)^2 - 8R_T}}{2}$$

Frame 8/74

Horton and Tokunaga are happy

Some observations:

- ▶ R_n and R_ℓ depend on T_1 and R_T .
- ▶ Seems that R_a must as well...
- ▶ Suggests Horton's laws must contain some redundancy
- ▶ We'll in fact see that $R_a = R_n$.
- ▶ Also: Both Tokunaga's law and Horton's laws can be generalized to relationships between non-trivial statistical distributions. [3, 4]

Branching Networks II

Horton ↔ Tokunaga

Reducing Horton

Scaling relations

Fluctuations

Models

Nutshell

References

Frame 9/74

Horton and Tokunaga are happy

The other way round

- ▶ Note: We can invert the expressions for R_n and R_ℓ to find Tokunaga's parameters in terms of Horton's parameters.

$$R_T = R_\ell,$$

$$T_1 = R_n - R_\ell - 2 + 2R_\ell/R_n.$$

- ▶ Suggests we should be able to argue that Horton's laws imply Tokunaga's laws (if drainage density is uniform)...

Frame 10/74

Horton and Tokunaga are friends

From Horton to Tokunaga [2]

- ▶ Assume Horton's laws hold for number and length
- ▶ Start with an order ω stream
- ▶ Scale up by a factor of R_ℓ , orders increment
- ▶ Maintain drainage density by adding new order 1 streams

Branching Networks II

Horton ↔ Tokunaga

Reducing Horton

Scaling relations

Fluctuations

Models

Nutshell

References

Frame 11/74

Horton and Tokunaga are friends

... and in detail:

- ▶ Must retain same drainage density.
- ▶ Add an extra $(R_\ell - 1)$ first order streams for each original tributary.
- ▶ Since number of first order streams is now given by T_{k+1} we have:

$$T_{k+1} = (R_\ell - 1) \left(\sum_{i=1}^k T_i + 1 \right).$$

- ▶ For large ω , Tokunaga's law is the solution—let's check...

References

Frame 12/74

Horton and Tokunaga are friends

Just checking:

- ▶ Substitute Tokunaga's law $T_i = T_1 R_\ell^{i-1} = T_1 R_\ell^{i-1}$ into

$$T_{k+1} = (R_\ell - 1) \left(\sum_{i=1}^k T_i + 1 \right)$$

▶

$$T_{k+1} = (R_\ell - 1) \left(\sum_{i=1}^k T_1 R_\ell^{i-1} + 1 \right)$$

$$= (R_\ell - 1) T_1 \left(\frac{R_\ell^k - 1}{R_\ell - 1} + 1 \right)$$

$$\simeq (R_\ell - 1) T_1 \frac{R_\ell^k}{R_\ell - 1} = T_1 R_\ell^k \quad \dots \text{yep.}$$

Frame 17/74

Reducing Horton's laws:

Rough first effort to show $R_n \equiv R_a$:

- ▶ $a_\Omega \propto$ sum of all stream lengths in a order Ω basin (assuming uniform drainage density)

▶ So:

$$\begin{aligned}
 a_\Omega &\simeq \sum_{\omega=1}^{\Omega} n_\omega \bar{s}_\omega / \rho_{dd} \\
 &\propto \sum_{\omega=1}^{\Omega} \underbrace{R_n^{\Omega-\omega}}_{n_\omega} \cdot \overbrace{1}^{n_\Omega} \underbrace{\bar{s}_1 \cdot R_s^{\omega-1}}_{\bar{s}_\omega} \\
 &= \frac{R_n^\Omega}{R_s} \bar{s}_1 \sum_{\omega=1}^{\Omega} \left(\frac{R_s}{R_n} \right)^\omega
 \end{aligned}$$

Branching Networks II

Horton \leftrightarrow
Tokunaga

Reducing Horton

Scaling relations

Fluctuations

Models

Nutshell

References

Frame 18/74

Reducing Horton's laws:

Continued ...

▶

$$\begin{aligned}
 a_\Omega &\propto \frac{R_n^\Omega}{R_s} \bar{s}_1 \sum_{\omega=1}^{\Omega} \left(\frac{R_s}{R_n} \right)^\omega \\
 &= \frac{R_n^\Omega}{R_s} \bar{s}_1 \frac{R_s}{R_n} \frac{1 - (R_s/R_n)^\Omega}{1 - (R_s/R_n)} \\
 &\sim R_n^{\Omega-1} \bar{s}_1 \frac{1}{1 - (R_s/R_n)} \text{ as } \Omega \nearrow
 \end{aligned}$$

- ▶ So, a_Ω is growing like R_n^Ω and therefore:

$$R_n \equiv R_a$$

Frame 22/74

Scaling laws

The story so far:

- ▶ Natural branching networks are **hierarchical**, **self-similar** structures
- ▶ Hierarchy is **mixed**
- ▶ Tokunaga's law describes detailed architecture: $T_k = T_1 R_T^{k-1}$.
- ▶ We have connected Tokunaga's and Horton's laws
- ▶ Only two Horton laws are independent ($R_n = R_a$)
- ▶ Only **two** parameters are **independent**: $(T_1, R_T) \Leftrightarrow (R_n, R_s)$

Branching Networks II

Horton ↔ Tokunaga

Reducing Horton

Scaling relations

Fluctuations

Models

Nutshell

References

Frame 23/74

Scaling laws

A little further...

- ▶ Ignore stream ordering for the moment
- ▶ Pick a random location on a branching network p .
- ▶ Each point p is associated with a basin and a longest stream length
- ▶ **Q:** What is probability that the p 's drainage basin has area a ? $P(a) \propto a^{-\tau}$ for large a
- ▶ **Q:** What is probability that the longest stream from p has length ℓ ? $P(\ell) \propto \ell^{-\gamma}$ for large ℓ
- ▶ Roughly observed: $1.3 \lesssim \tau \lesssim 1.5$ and $1.7 \lesssim \gamma \lesssim 2.0$

Frame 27/74

Scaling laws

Finding γ :

- ▶ The connection between $P(x)$ and $P_{>}(x)$ when $P(x)$ has a power law tail is simple:
- ▶ Given $P(\ell) \sim \ell^{-\gamma}$ large ℓ then for large enough l_*

$$\begin{aligned}
 P_{>}(l_*) &= \int_{l=l_*}^{l_{\max}} P(\ell) d\ell \\
 &\sim \int_{l=l_*}^{l_{\max}} \ell^{-\gamma} d\ell \\
 &= \frac{\ell^{-\gamma+1}}{-\gamma+1} \Big|_{l=l_*}^{l_{\max}} \\
 &\propto l_*^{-\gamma+1} \quad \text{for } l_{\max} \gg l_*
 \end{aligned}$$

Branching Networks II

Horton ↔ Tokunaga

Reducing Horton

Scaling relations

Fluctuations

Models

Nutshell

References

Frame 28/74

Scaling laws

Finding γ :

- ▶ **Aim:** determine probability of randomly choosing a point on a network with main stream length $> l_*$
- ▶ Assume some spatial sampling resolution Δ
- ▶ Landscape is broken up into grid of $\Delta \times \Delta$ sites
- ▶ Approximate $P_{>}(l_*)$ as

$$P_{>}(l_*) = \frac{N_{>}(l_*; \Delta)}{N_{>}(0; \Delta)}$$

where $N_{>}(l_*; \Delta)$ is the number of sites with main stream length $> l_*$.

- ▶ Use Horton's law of stream segments:
 $s_\omega / s_{\omega-1} = R_s \dots$

Scaling laws

Finding γ :

- ▶ Set $l_* = l_\omega$ for some $1 \ll \omega \ll \Omega$.

$$P_{>}(l_\omega) = \frac{N_{>}(l_\omega; \Delta)}{N_{>}(0; \Delta)} \simeq \frac{\sum_{\omega'=\omega+1}^{\Omega} n_{\omega'} s_{\omega'} / \Delta}{\sum_{\omega'=1}^{\Omega} n_{\omega'} s_{\omega'} / \Delta}$$

- ▶ Δ 's cancel
- ▶ Denominator is $a_{\Omega} \rho_{\text{dd}}$, a constant.
- ▶ So... using Horton's laws...

$$P_{>}(l_\omega) \propto \sum_{\omega'=\omega+1}^{\Omega} n_{\omega'} s_{\omega'} \simeq \sum_{\omega'=\omega+1}^{\Omega} (1 \cdot R_n^{\Omega-\omega'}) (\bar{s}_1 \cdot R_s^{\omega'-1})$$

Scaling laws

Finding γ :

- ▶ We are here:

$$P_{>}(l_\omega) \propto \sum_{\omega'=\omega+1}^{\Omega} (1 \cdot R_n^{\Omega-\omega'}) (\bar{s}_1 \cdot R_s^{\omega'-1})$$

- ▶ Cleaning up irrelevant constants:

$$P_{>}(l_\omega) \propto \sum_{\omega'=\omega+1}^{\Omega} \left(\frac{R_s}{R_n} \right)^{\omega'}$$

- ▶ Change summation order by substituting $\omega'' = \Omega - \omega'$.
- ▶ Sum is now from $\omega'' = 0$ to $\omega'' = \Omega - \omega - 1$ (equivalent to $\omega' = \Omega$ down to $\omega' = \omega + 1$)

Scaling laws

Finding γ :

$$P_{>}(l_\omega) \propto \sum_{\omega''=0}^{\Omega-\omega-1} \left(\frac{R_s}{R_n} \right)^{\Omega-\omega''} \propto \sum_{\omega''=0}^{\Omega-\omega-1} \left(\frac{R_n}{R_s} \right)^{\omega''}$$

- ▶ Since $R_n > R_s$ and $1 \ll \omega \ll \Omega$,

$$P_{>}(l_\omega) \propto \left(\frac{R_n}{R_s} \right)^{\Omega-\omega} \propto \left(\frac{R_n}{R_s} \right)^{-\omega}$$

again using $\sum_{i=0}^{n-1} a^i = (a^n - 1)/(a - 1)$

Scaling laws

Finding γ :

- ▶ Nearly there:

$$P_{>}(l_{\omega}) \propto \left(\frac{R_n}{R_s}\right)^{-\omega} = e^{-\omega \ln(R_n/R_s)}$$

- ▶ Need to express right hand side in terms of l_{ω} .
- ▶ Recall that $l_{\omega} \simeq \bar{l}_1 R_{\ell}^{\omega-1}$.
- ▶

$$l_{\omega} \propto R_{\ell}^{\omega} = R_s^{\omega} = e^{\omega \ln R_s}$$

Frame 36/74

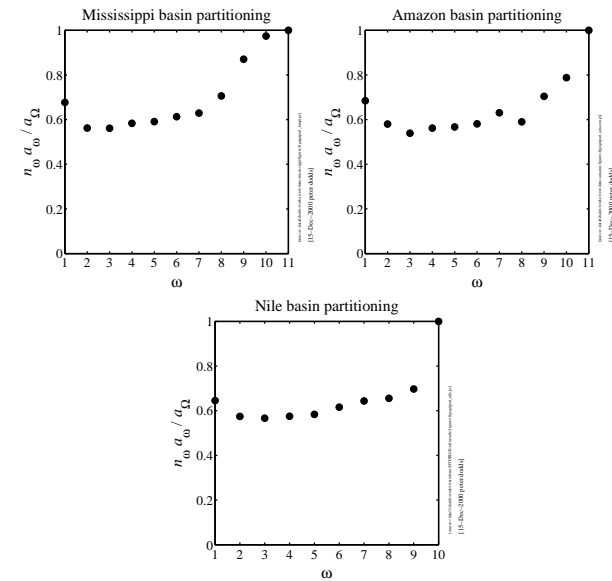

Connecting exponents

Only 3 parameters are independent:
e.g., take d , R_n , and R_s

relation:	scaling relation/parameter: [2]
$l \sim L^d$	d
$T_k = T_1(R_T)^{k-1}$	$T_1 = R_n - R_s - 2 + 2R_s/R_n$ $R_T = R_s$
$n_\omega/n_{\omega+1} = R_n$	R_n
$\bar{a}_{\omega+1}/\bar{a}_\omega = R_a$	$R_a = R_n$
$\bar{l}_{\omega+1}/\bar{l}_\omega = R_l$	$R_l = R_s$
$l \sim a^h$	$h = \log R_s / \log R_n$
$a \sim L^D$	$D = d/h$
$L_\perp \sim L^H$	$H = d/h - 1$
$P(a) \sim a^{-\tau}$	$\tau = 2 - h$
$P(l) \sim l^{-\gamma}$	$\gamma = 1/h$
$\Lambda \sim a^\beta$	$\beta = 1 + h$
$\lambda \sim L^\varphi$	$\varphi = d$

Equipartitioning reexamined:

Recall this story:

Equipartitioning

- ▶ What about

$$P(a) \sim a^{-\tau} \quad ?$$

- ▶ Since $\tau > 1$, suggests no equipartitioning:

$$aP(a) \sim a^{-\tau+1} \neq \text{const}$$

- ▶ $P(a)$ overcounts basins within basins...
- ▶ while stream ordering separates basins...

Fluctuations

Moving beyond the mean:

- ▶ Both Horton's laws and Tokunaga's law relate average properties, e.g.,

$$\bar{s}_\omega / \bar{s}_{\omega-1} = R_s$$

- ▶ Natural generalization to consideration relationships between **probability distributions**
- ▶ Yields rich and full description of branching network structure
- ▶ See into the heart of randomness...

A toy model—Scheidegger’s model

Directed random networks [11, 12]

$$P(\searrow) = P(\swarrow) = 1/2$$

Generalizing Horton's laws

- ▶ Sum of variables $l_\omega = \sum_{\mu=1}^{\mu=\omega} s_\mu$ leads to convolution of distributions:

$$N(l|\omega) = N(s|1) * N(s|2) * \dots * N(s|\omega)$$

$$N(s|\omega) = \frac{1}{R_n^\omega R_l^\omega} F(s/R_l^\omega)$$

$$F(x) = e^{-x/\xi}$$

Mississippi: $\xi \simeq 900$ m.

Generalizing Tokunaga's law

So

$$P(T_{\mu,\nu}) = (R_s)^{\mu-\nu-1} P_t \left[T_{\mu,\nu} / (R_s)^{\mu-\nu-1} \right]$$

where

$$P_t(z) = \frac{1}{\xi_t} e^{-z/\xi_t}$$

$$P(s_\mu) \Leftrightarrow P(T_{\mu,\nu})$$

- ▶ Exponentials arise from randomness.
- ▶ Look at joint probability $P(s_\mu, T_{\mu,\nu})$.

Frame 52/74

Generalizing Tokunaga's law

- ▶ Follow stream segments down stream from their beginning
- ▶ Probability (or rate) of an order μ stream segment terminating is **constant**:

$$\tilde{p}_\mu \simeq 1/(R_s)^{\mu-1} \xi_s$$

- ▶ Probability decays exponentially with stream order
- ▶ Inter-tributary lengths exponentially distributed
- ▶ \Rightarrow random spatial distribution of stream segments

Generalizing Tokunaga's law

- ▶ Joint distribution for generalized version of Tokunaga's law:

$$P(s_\mu, T_{\mu,\nu}) = \tilde{p}_\mu \binom{s_\mu - 1}{T_{\mu,\nu}} \rho_\nu^{T_{\mu,\nu}} (1 - \rho_\nu - \tilde{p}_\mu)^{s_\mu - T_{\mu,\nu} - 1}$$

where

- ▶ ρ_ν = probability of absorbing an order ν side stream
- ▶ \tilde{p}_μ = probability of an order μ stream terminating
- ▶ Approximation: depends on distance units of s_μ
- ▶ In each unit of distance along stream, there is one chance of a side stream entering or the stream terminating.

Generalizing Tokunaga's law

- ▶ Now deal with thing:

$$P(s_\mu, T_{\mu,\nu}) = \tilde{p}_\mu \binom{s_\mu - 1}{T_{\mu,\nu}} \rho_\nu^{T_{\mu,\nu}} (1 - \rho_\nu - \tilde{p}_\mu)^{s_\mu - T_{\mu,\nu} - 1}$$

- ▶ Set $(x, y) = (s_\mu, T_{\mu,\nu})$ and $q = 1 - \rho_\nu - \tilde{p}_\mu$, approximate liberally.

- ▶ Obtain

$$P(x, y) = Nx^{-1/2} [F(y/x)]^x$$

where

$$F(v) = \left(\frac{1-v}{q} \right)^{-(1-v)} \left(\frac{v}{p} \right)^{-v}$$

Generalizing Tokunaga's law

- ▶ Checking form of $P(s_\mu, T_{\mu,\nu})$ works:

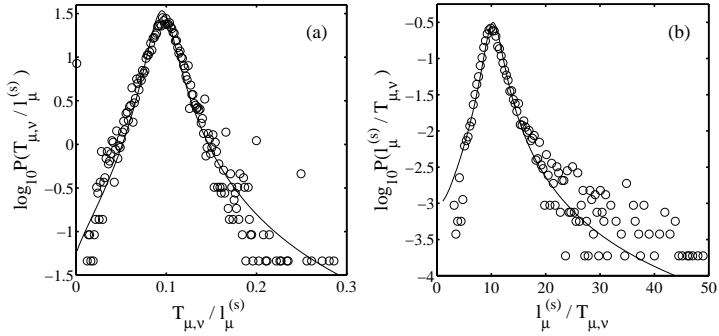

Scheidegger:

Branching networks II Key Points:

- ▶ Horton's laws and Tokunaga law all fit together.
- ▶ nb. for 2-d networks, these laws are 'planform' laws and ignore slope.
- ▶ Abundant scaling relations can be derived.
- ▶ Can take R_n , R_ℓ , and d as three independent parameters necessary to describe all 2-d branching networks.
- ▶ For scaling laws, only $h = \ln R_\ell / \ln R_n$ and d are needed.
- ▶ Laws can be extended nicely to laws of distributions.
- ▶ Numerous models of branching network evolution exist: nothing rock solid yet.
