Contagion models

Some large questions concerning network contagion:

1. For a given **spreading mechanism** on a given network, what's the **probability** that there will be **global spreading**?
 2. If spreading does take off, how far will it go?
 3. How do the **details** of the **network** affect the outcome?
 4. How do the **details** of the **spreading mechanism** affect the outcome?
 5. What if the **seed** is one or many nodes?
- **Next up:** We'll look at some fundamental kinds of spreading on generalized random networks.

Frame 3/58

Spreading mechanisms

■ uninfected
■ infected

- **General spreading mechanism:** State of node i depends on history of i and i 's neighbors' states.
- **Doses** of entity may be stochastic and history-dependent.
- May have **multiple, interacting entities** spreading at once.

Frame 4/58

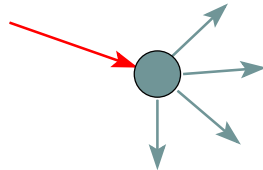

Spreading on Random Networks

- ▶ For random networks, we know local structure is pure branching.
- ▶ Successful spreading is \therefore contingent on **single edges** infecting nodes.

Success

Failure:

- ▶ Focus on **binary** case with edges and nodes either infected or not.

Frame 5/58

Contagion condition

- ▶ We need to find:
 - r = the average # of infected edges that one random infected edge brings about.
- ▶ Define β_k as the probability that a node of degree k is infected by a single infected edge.

$$r = \sum_{k=0}^{\infty} \underbrace{\frac{kP_k}{\langle k \rangle}}_{\text{prob. of connecting to a degree } k \text{ node}} \cdot \underbrace{\beta_k}_{\text{Prob. of infection}} \cdot \underbrace{(k-1)}_{\text{\# outgoing infected edges}}$$

$$+ \sum_{k=0}^{\infty} \underbrace{\frac{kP_k}{\langle k \rangle}}_{\text{prob. of connecting to a degree } k \text{ node}} \cdot \underbrace{(1-\beta_k)}_{\text{Prob. of no infection}} \cdot \underbrace{0}_{\text{\# outgoing infected edges}}$$

Frame 6/58

Contagion condition

- ▶ Our contagion condition is then:

$$r = \sum_{k=0}^{\infty} \frac{(k-1)kP_k}{\langle k \rangle} \beta_k > 1.$$

- ▶ **Case 1:** If $\beta_k = 1$ then

$$r = \frac{\langle k(k-1) \rangle}{\langle k \rangle} > 1.$$

- ▶ **Good:** This is just our giant component condition again.

Contagion

Basic Contagion Models

Social Contagion Models

Network version
All-to-all networks
Theory

References

Frame 7/58

Contagion condition

- ▶ **Case 2:** If $\beta_k = \beta < 1$ then

$$r = \beta \frac{\langle k(k-1) \rangle}{\langle k \rangle} > 1.$$

- ▶ A fraction $(1-\beta)$ of edges do not transmit infection.
- ▶ Analogous phase transition to giant component case but **critical value** of $\langle k \rangle$ is **increased**.
- ▶ Aka **bond percolation**.
- ▶ Resulting degree distribution P'_k :

$$P'_k = \beta^k \sum_{i=k}^{\infty} \binom{i}{k} (1-\beta)^{i-k} P_i.$$

- ▶ We can show $F_{P'}(x) = F_P(\beta x + 1 - \beta)$.

Network version
All-to-all networks
Theory

References

Frame 8/58

Contagion condition

- ▶ **Cases 3, 4, 5, ...:** Now allow β_k to depend on k
- ▶ **Asymmetry:** Transmission along an edge depends on node's degree at other end.
- ▶ Possibility: β_k increases with k ... **unlikely.**
- ▶ Possibility: β_k is not monotonic in k ... **unlikely.**
- ▶ Possibility: β_k decreases with k ... **hmmm.**
- ▶ $\beta_k \searrow$ is a plausible representation of a simple kind of social contagion.
- ▶ **The story:**
More well connected people are harder to influence.

Contagion

- Basic Contagion Models
- Social Contagion Models
- Network version
- All-to-all networks
- Theory
- References

Frame 9/58

Contagion condition

- ▶ **Example:** $\beta_k = 1/k$.

$$r = \sum_{k=1}^{\infty} \frac{(k-1)kP_k}{\langle k \rangle} \beta_k = \sum_{k=1}^{\infty} \frac{(k-1)kP_k}{\langle k \rangle k}$$

$$= \sum_{k=1}^{\infty} \frac{(k-1)P_k}{\langle k \rangle} = \frac{\langle k \rangle - 1}{\langle k \rangle} = 1 - \frac{1}{\langle k \rangle}$$

- ▶ Since r is always less than 1, no spreading can occur for this mechanism.
- ▶ Decay of β_k is too fast.
- ▶ Result is independent of degree distribution.

Contagion

- Basic Contagion Models
- Social Contagion Models
- Network version
- All-to-all networks

Frame 10/58

Contagion condition

- ▶ **Example:** $\beta_k = H(\frac{1}{k} - \phi)$
where $0 < \phi \leq 1$ is a **threshold** and H is the Heaviside function.
- ▶ Infection only occurs for nodes with **low** degree.
- ▶ Call these nodes **vulnerables**:
they flip when **only one** of their friends flips.

$$r = \sum_{k=1}^{\infty} \frac{(k-1)kP_k}{\langle k \rangle} \beta_k = \sum_{k=1}^{\infty} \frac{(k-1)kP_k}{\langle k \rangle} H(\frac{1}{k} - \phi)$$

$$= \sum_{k=1}^{\lfloor \frac{1}{\phi} \rfloor} \frac{(k-1)kP_k}{\langle k \rangle} \quad \text{where } \lfloor \cdot \rfloor \text{ means floor.}$$

Frame 11/58

Contagion condition

- ▶ The contagion condition:

$$r = \sum_{k=1}^{\lfloor \frac{1}{\phi} \rfloor} \frac{(k-1)kP_k}{\langle k \rangle} > 1.$$

- ▶ As $\phi \rightarrow 1$, all nodes become resilient and $r \rightarrow 0$.
- ▶ As $\phi \rightarrow 0$, all nodes become vulnerable and the contagion condition matches up with the giant component condition.
- ▶ **Key:** If we fix ϕ and then vary $\langle k \rangle$, we may see **two** phase transitions.
- ▶ Added to our standard giant component transition, we will see a cut off in spreading as nodes become more connected.

Social Contagion

Granovetter's Threshold model—recap

- ▶ Assumes deterministic response functions
- ▶ ϕ_* = threshold of an individual.
- ▶ $f(\phi_*)$ = distribution of thresholds in a population.
- ▶ $F(\phi_*)$ = cumulative distribution = $\int_{\phi'_*=0}^{\phi_*} f(\phi'_*)d\phi'_*$
- ▶ ϕ_t = fraction of people 'rioting' at time step t .

Social Sciences—Threshold models

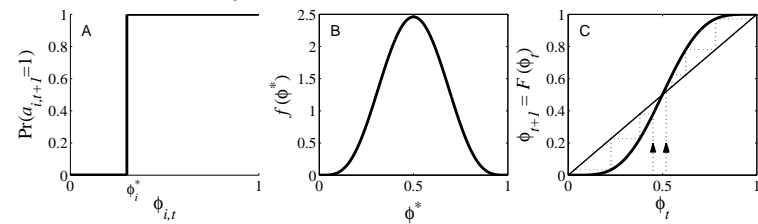

- ▶ At time $t + 1$, fraction rioting = fraction with $\phi_* \leq \phi_t$.

$$\phi_{t+1} = \int_0^{\phi_t} f(\phi_*)d\phi_* = F(\phi_*)|_0^{\phi_t} = F(\phi_t)$$

- ▶ \Rightarrow Iterative maps of the unit interval $[0, 1]$.

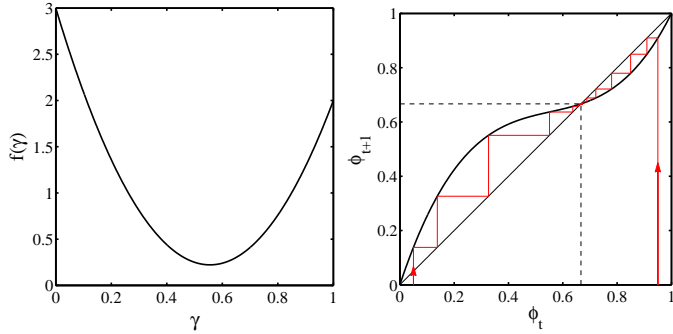

Social Sciences—Threshold models

Action based on perceived behavior of others.

- ▶ Two states: S and I
- ▶ Recover now possible (SIS)
- ▶ ϕ = fraction of contacts 'on' (e.g., rioting)
- ▶ Discrete time, synchronous update (strong assumption!)
- ▶ This is a **Critical mass model**

Social Sciences—Threshold models

▶ Example of single stable state model

Social Sciences—Threshold models

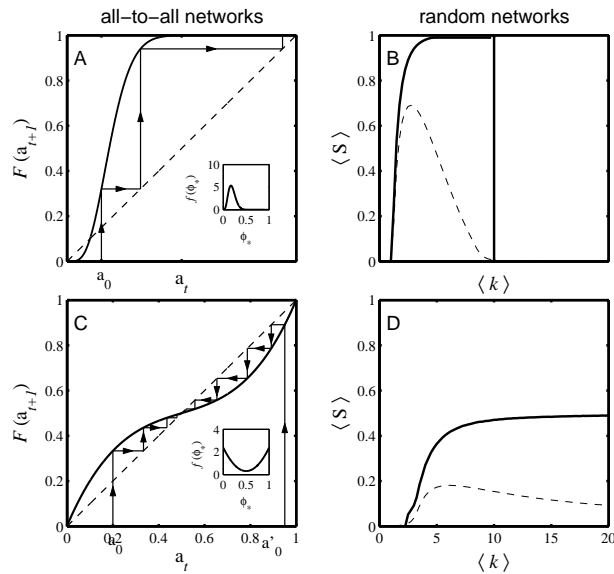

Implications for collective action theory:

1. Collective uniformity $\not\Rightarrow$ individual uniformity
2. Small individual changes \Rightarrow large global changes

Next:

- ▶ Connect mean-field model to network model.
- ▶ Single seed for network model: $1/N \rightarrow 0$.
- ▶ Comparison between network and mean-field model sensible for vanishing seed size for the latter.

All-to-all versus random networks

Threshold contagion on random networks

Three key pieces to describe analytically:

1. The fractional size of the largest subcomponent of vulnerable nodes, S_{vuln} .
2. The chance of starting a global spreading event, $P_{\text{trig}} = S_{\text{trig}}$.
3. The expected final size of any successful spread, S .
 - ▶ n.b., the distribution of S is almost always bimodal.

Threshold contagion on random networks

- ▶ **First goal:** Find the largest component of vulnerable nodes.
- ▶ Recall that for finding the giant component's size, we had to solve:

$$F_\pi(x) = xF_P(F_\rho(x)) \text{ and } F_\rho(x) = xF_R(F_\rho(x))$$

- ▶ We'll find a similar result for the subset of nodes that are vulnerable.
- ▶ This is a node-based percolation problem.
- ▶ For a general monotonic threshold distribution $f(\phi)$, a degree k node is vulnerable with probability

$$\beta_k = \int_0^{1/k} f(\phi) d\phi.$$

Threshold contagion on random networks

- ▶ Everything now revolves around the **modified** generating function:

$$F_P^{(\text{vuln})}(x) = \sum_{k=0}^{\infty} \beta_k P_k x^k.$$

- ▶ Generating function for friends-of-friends distribution is related in same way as before:

$$F_R^{(\text{vuln})}(x) = \frac{\frac{d}{dx} F_P^{(\text{vuln})}(x)}{\frac{d}{dx} F_P^{(\text{vuln})}(x)|_{x=1}}.$$

Threshold contagion on random networks

- ▶ Functional relations for component size g.f.'s are almost the same...

$$F_\pi^{(\text{vuln})}(x) = \underbrace{1 - F_P^{(\text{vuln})}(1)}_{\substack{\text{central node} \\ \text{is not} \\ \text{vulnerable}}} + xF_P^{(\text{vuln})}(F_\rho^{(\text{vuln})}(x))$$

$$F_\rho^{(\text{vuln})}(x) = \underbrace{1 - F_R^{(\text{vuln})}(1)}_{\substack{\text{first node} \\ \text{is not} \\ \text{vulnerable}}} + xF_R^{(\text{vuln})}(F_\rho^{(\text{vuln})}(x))$$

- ▶ Can now solve as before to find $S_{\text{vuln}} = 1 - F_\pi^{(\text{vuln})}(1)$.

Threshold contagion on random networks

- ▶ **Second goal:** Find probability of triggering largest vulnerable component.
- ▶ Assumption is **first node** is **randomly chosen**.
- ▶ **Same set up** as for vulnerable component except now we don't care if the initial node is vulnerable or not:

$$F_\pi^{(\text{trig})}(x) = xF_P(F_\rho^{(\text{vuln})}(x))$$

$$F_\rho^{(\text{vuln})}(x) = 1 - F_R^{(\text{vuln})}(1) + xF_R^{(\text{vuln})}(F_\rho^{(\text{vuln})}(x))$$

- ▶ Solve as before to find $P_{\text{trig}} = S_{\text{trig}} = 1 - F_\pi^{(\text{trig})}(1)$.

Threshold contagion on random networks

- ▶ **Third goal:** Find expected fractional size of spread.
- ▶ Not obvious even for uniform threshold problem.
- ▶ Difficulty is in figuring out if and when nodes that need ≥ 2 hits switch on.
- ▶ Problem **solved** for infinite seed case by Gleeson and Cahalane:
 "Seed size strongly affects cascades on random networks," Phys. Rev. E, 2007. [6]
- ▶ Developed further by Gleeson in "Cascades on correlated and modular random networks," Phys. Rev. E, 2008. [5]

Frame 37/58

Expected size of spread

Idea:

- ▶ Randomly turn on a fraction ϕ_0 of nodes at time $t = 0$
- ▶ Capitalize on local branching network structure of random networks (again)
- ▶ Now think about what must happen for a specific node i to become active at time t :
 - $t = 0$: i is one of the seeds (prob = ϕ_0)
 - $t = 1$: i was not a seed but enough of i 's friends switched on at time $t = 0$ so that i 's threshold is now exceeded.
 - $t = 2$: enough of i 's friends and friends-of-friends switched on at time $t = 0$ so that i 's threshold is now exceeded.
 - $t = n$: enough nodes within n hops of i switched on at $t = 0$ and their effects have propagated to reach i .

Frame 40/58

Expected size of spread

Notes:

- ▶ Calculations are possible nodes do not become inactive.
- ▶ Not just for threshold model—works for a wide range of contagion processes.
- ▶ We can analytically determine the entire time evolution, not just the final size.
- ▶ We can in fact determine $\Pr(\text{node of degree } k \text{ switches on at time } t)$.
- ▶ Asynchronous updating can be handled too.

Contagion

Basic Contagion Models
Social Contagion Models
Network version
All-to-all networks
Theory
References

Frame 41/58

Expected size of spread

Pleasantness:

- ▶ Taking off from a single seed story is about **expansion** away from a node.
- ▶ Extent of spreading story is about **contraction** at a node.

Contagion

Network version
All-to-all networks
Theory
References

Frame 42/58

Expected size of spread

- ▶ **Notation:** $\Pr(\text{node } i \text{ becomes active at time } t) = \phi_{i,t}$.
- ▶ **Notation:** $\beta_{kj} = \Pr(\text{a degree } k \text{ node becomes active if } j \text{ neighbors are active})$.
- ▶ Our starting point: $\phi_{i,0} = \phi_0$.
- ▶ $\binom{k_i}{j} \phi_0^j (1 - \phi_0)^{k_i - j} = \Pr(j \text{ of node } i\text{'s } k_i \text{ neighbors were seeded at time } t = 0)$.
- ▶ Probability node i was a seed at $t = 0$ is ϕ_0 (as above).
- ▶ Probability node i was not a seed at $t = 0$ is $(1 - \phi_0)$.
- ▶ Combining everything, we have:

$$\phi_{i,1} = \phi_0 + (1 - \phi_0) \sum_{j=0}^{k_i} \binom{k_i}{j} \phi_0^j (1 - \phi_0)^{k_i - j} \beta_{k_i j}$$

Frame 44/58

Expected size of spread

First connect θ_0 to θ_1 :

▶ $\theta_1 = \phi_0 +$

$$(1 - \phi_0) \sum_{k=1}^{\infty} \frac{kP_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_0^j (1 - \theta_0)^{k-1-j} \beta_{kj}$$

- ▶ $\frac{kP_k}{\langle k \rangle} = R_k = \mathbf{Pr}$ (edge connects to a degree k node).
- ▶ $\sum_{j=0}^{k-1}$ piece gives \mathbf{Pr} (degree node k activates) of its neighbors $k - 1$ incoming neighbors are active.
- ▶ ϕ_0 and $(1 - \phi_0)$ terms account for state of node at time $t = 0$.
- ▶ See this all generalizes to give θ_{t+1} in terms of θ_t ...

Expected size of spread

Two pieces:

1. $\theta_{t+1} = \phi_0 +$

$$(1 - \phi_0) \sum_{k=1}^{\infty} \frac{kP_k}{\langle k \rangle} \sum_{j=0}^{k-1} \binom{k-1}{j} \theta_t^j (1 - \theta_t)^{k-1-j} \beta_{kj}$$

with $\theta_0 = \phi_0$.

2. $\phi_{t+1} = \phi_0 +$

$$(1 - \phi_0) \sum_{k=0}^{\infty} P_k \sum_{j=0}^k \binom{k}{j} \theta_t^j (1 - \theta_t)^{k-j} \beta_{kj}$$

Comparison between theory and simulations

- ▶ Pure random networks with simple threshold responses
- ▶ $R =$ uniform threshold (our ϕ_*); $z =$ average degree; $\rho = \phi$; $q = \theta$; $N = 10^5$.
- ▶ $\phi_0 = 10^{-3}$, 0.5×10^{-2} , and 10^{-2} .
- ▶ Cascade window is for $\phi = 10^{-2}$ case.
- ▶ Sensible expansion of cascade window as ϕ_0 increases.

From Gleeson and Cahalane [6]

Notes:

- ▶ Retrieve cascade condition for spreading from a single seed in limit $\phi_0 \rightarrow 0$.
- ▶ Depends on map $\theta_{t+1} = G(\theta_t; \phi_0)$.
- ▶ First: if self-starters are present, some activation is assured:

$$G(0; \phi_0) = \sum_{k=1}^{\infty} \frac{kP_k}{\langle k \rangle} \beta_{k0} > 0.$$

meaning $\beta_{k0} > 0$ for at least one value of $k \geq 1$.

- ▶ If $\theta = 0$ is a fixed point of G (i.e., $G(0; \phi_0) = 0$) then spreading occurs if

$$G'(0; \phi_0) = \frac{1}{\langle k \rangle} \sum_{k=0}^{\infty} (k-1)kP_k \beta_{k1} > 1.$$

Insert question from assignment 5 (田)

Notes:

In words:

- ▶ If $G(0; \phi_0) > 0$, spreading must occur because some nodes turn on for free.
- ▶ If G has an **unstable fixed point** at $\theta = 0$, then cascades are also always possible.

Non-vanishing seed case:

- ▶ Cascade condition is more complicated for $\phi_0 > 0$.
- ▶ If G has a **stable fixed point** at $\theta = 0$, and an **unstable fixed point** for some $0 < \theta_* < 1$, then for $\theta_0 > \theta_*$, spreading takes off.
- ▶ Tricky point: G depends on ϕ_0 , so as we change ϕ_0 , we also change G .

Comparison between theory and simulations

- ▶ Now allow thresholds to be distributed according to a Gaussian with mean R .
- ▶ $R = 0.2, 0.362$, and 0.38 ; $\sigma = 0.2$.
- ▶ $\phi_0 = 0$ but some nodes have thresholds ≤ 0 so effectively $\phi_0 > 0$.
- ▶ Now see a (nasty) discontinuous phase transition for low $\langle k \rangle$.

From Gleeson and Cahalane^[6]

General fixed point story:

- ▶ Given $\theta_0 (= \phi_0)$, θ_∞ will be the nearest stable fixed point, either above or below.
- ▶ n.b., adjacent fixed points must have opposite stability types.
- ▶ **Important:** Actual form of G depends on ϕ_0 .
- ▶ So choice of ϕ_0 dictates both G and starting point—can't start anywhere for a given G .

Comparison between theory and simulations

- ▶ Plots of stability points for $\theta_{t+1} = G(\theta_t; \phi_0)$.
- ▶ n.b.: 0 is not a fixed point here: $\theta_0 = 0$ always takes off.
- ▶ Top to bottom: $R = 0.35, 0.371$, and 0.375 .
- ▶ n.b.: higher values of θ_0 for (b) and (c) lead to higher fixed points of G .
- ▶ Saddle node bifurcations appear and merge (b and c).

From Gleeson and Cahalane^[6]

Spreadarama

Bridging to single seed case:

- ▶ Consider largest vulnerable component as initial set of seeds.
- ▶ Not quite right as spreading must move through vulnerables.
- ▶ But we can usefully think of the vulnerable component as activating at time $t = 0$ because order doesn't matter.
- ▶ Rebuild ϕ_t and θ_t expressions...
