# Generalized contagion model

#### Basic questions about contagion

- How many types of contagion are there?
- How can we categorize real-world contagions?
- Can we connect models of disease-like and social contagion?
- Focus: mean field models.

Mathematical Epidemiology (recap)

#### The standard SIR model [10]

- = basic model of disease contagion
- Three states:
  - 1. S = Susceptible
  - 2. I = Infective/Infectious
  - 3. R = Recovered or Removed or Refractory
- ► S(t) + I(t) + R(t) = 1
- Presumes random interactions (mass-action principle)
- Interactions are independent (no memory)
- Discrete and continuous time versions

# Independent Interaction Models

Discrete time automata example:

Transition Probabilities:

 $\beta$  for being infected given contact with infected *r* for recovery  $\rho$  for loss of immunity

# Independent Interaction models

Differential equations for continuous model

$$\frac{\mathrm{d}}{\mathrm{d}t}S = -\beta IS + \rho R$$
$$\frac{\mathrm{d}}{\mathrm{d}t}I = \beta IS - rI$$
$$\frac{\mathrm{d}}{\mathrm{d}t}R = rI - \rho R$$

 $\beta$ , *r*, and  $\rho$  are now rates.

# Reproduction Number $R_0$ :

- R<sub>0</sub> = expected number of infected individuals resulting from a single initial infective
- Epidemic threshold: If  $R_0 > 1$ , 'epidemic' occurs.

# Independent Interaction Models

#### Original models attributed to

- ▶ 1920's: Reed and Frost
- 1920's/1930's: Kermack and McKendrick<sup>[7, 9, 8]</sup>
- Coupled differential equations with a mass-action principle

# Reproduction Number R<sub>0</sub>

#### Discrete version:

- Set up: One Infective in a randomly mixing population of Susceptibles
- At time t = 0, single infective random bumps into a Susceptible
- Probability of transmission =  $\beta$
- ► At time t = 1, single Infective remains infected with probability 1 - r
- At time t = k, single Infective remains infected with probability  $(1 r)^k$

# Reproduction Number R<sub>0</sub>

Discrete version:

Expected number infected by original Infective:

$$R_0 = \beta + (1 - r)\beta + (1 - r)^2\beta + (1 - r)^3\beta + \dots$$
$$= \beta \left( 1 + (1 - r) + (1 - r)^2 + (1 - r)^3 + \dots \right)$$
$$= \beta \frac{1}{1 - (1 - r)} = \frac{\beta}{r}$$

Similar story for continuous model.

Simple disease spreading models

Valiant attempts to use SIR and co. elsewhere:

- Adoption of ideas/beliefs (Goffman & Newell, 1964)<sup>[6]</sup>
- ▶ Spread of rumors (Daley & Kendall, 1964, 1965)<sup>[2, 3]</sup>
- Diffusion of innovations (Bass, 1969)<sup>[1]</sup>
- Spread of fanatical behavior (Castillo-Chávez & Song, 2003)

# Some (of many) issues

- Disease models assume independence of infectious events.
- Threshold models only involve proportions:  $3/10 \equiv 30/100.$
- Threshold models ignore exact sequence of influences
- Threshold models assume immediate polling.
- Mean-field models neglect network structure
- Network effects only part of story: media, advertising, direct marketing.

# Generalized model—ingredients

# $S \Rightarrow I$

Individuals 'remember' last T contacts:

$$D_{t,i} = \sum_{t'=t-T+1}^t d_i(t')$$

Infection occurs if individual i's 'threshold' is exceeded:

$$D_{t,i} \geq d_i^{s}$$

• Threshold  $d_i^*$  drawn from arbitrary distribution g at t = 0.

# Generalized model

## **Basic ingredients:**

- Incorporate memory of a contagious element<sup>[4, 5]</sup>
- Population of N individuals, each in state S, I, or R.
- Each individual randomly contacts another at each time step.
- $\phi_t$  = fraction infected at time t = probability of contact with infected individual
- With probability p, contact with infective leads to an exposure.
- If exposed, individual receives a dose of size d drawn from distribution f. Otherwise d = 0.

# A visual explanation

# Homogeneous, one hit models:

Fixed points for r < 1,  $d^* = 1$ , and T = 1:

- r < 1 means recovery is probabilistic.</p>
- $\blacktriangleright$  T = 1 means individuals forget past interactions.
- $d^* = 1$  means one positive interaction will infect an individual.
- Evolution of infection level:

 $\phi_{t+1} = \underbrace{p\phi_t}_{\mathbf{a}} + \underbrace{\phi_t(1-p\phi_t)}_{\mathbf{b}} \underbrace{(1-r)}_{\mathbf{c}}.$ 

- a: Fraction infected between t and t + 1, independent of past state or recovery.
- b: Probability of being infected and not being reinfected.
- c: Probability of not recovering.

# Generalized mean-field model

#### Study SIS-type contagion first:

 Recovered individuals are immediately susceptible again:

 $r = \rho = 1.$ 

- Look for steady-state behavior as a function of exposure probability p.
- Denote fixed points by  $\phi^*$ .

#### Homogeneous version:

- All individuals have threshold d\*
- ► All dose sizes are equal: d = 1

Frame 18/63 **日** りへで

Generalized

Contagion

ntroduction

ndependent nteraction models

nteraction model

Generalized Mode

Homogeneous, one hit models:
Fixed points for $r < 1$ , $d^* = 1$ , and $T = 1$ :
• Set $\phi_t = \phi^*$ :
$\phi^* = \boldsymbol{p}\phi^* + (1-\boldsymbol{p}\phi^*)\phi^*(1-r)$

$$\Rightarrow 1 = p + (1 - p\phi^*)(1 - r), \quad \phi^* \neq 0,$$

 $\Rightarrow \phi^* = \frac{1 - r/p}{1 - r}$  and  $\phi^* = 0$ .

- Critical point at  $p = p_c = r$ .
- Spreading takes off if p/r > 1
- Find continuous phase transition as for SIR model.
- Goodness: Matches  $R_o = \beta/\gamma > 1$  condition.

# Simple homogeneous examples

Fixed points for r = 1,  $d^* = 1$ , and T > 1

- > r = 1 means recovery is immediate.
- T > 1 means individuals remember at least 2 interactions.
- d\* = 1 means only one positive interaction in past T interactions will infect individual.
- Effect of individual interactions is independent from effect of others.
- Call  $\phi^*$  the steady state level of infection.
- Pr(infected) = 1 Pr(uninfected):

$$\phi^* = \mathbf{1} - (\mathbf{1} - \boldsymbol{p}\phi^*)^T$$

# Homogeneous, one hit models:

Fixed points for  $r \leq 1$ ,  $d^* = 1$ , and  $T \geq 1$ 

Start with r = 1, d<sup>∗</sup> = 1, and T ≥ 1 case we have just examined:

$$\phi^* = \mathbf{1} - (\mathbf{1} - \boldsymbol{p}\phi^*)^T.$$

- ► For *r* < 1, add to right hand side fraction who:
  - Did not receive any infections in last T time steps,
     And did not recover from a previous infection.
- Define corresponding dose histories. Example:

$$H_{1} = \{\dots, d_{t-T-2}, d_{t-T-1}, 1, \underbrace{0, 0, \dots, 0, 0}_{T \text{ 0's}}\},\$$

► With history *H*<sub>1</sub>, probability of being infected (not recovering in one time step) is 1 − *r*.

Homogeneous, one hit models: Fixed points for r = 1,  $d^* = 1$ , and T > 1

• Closed form expression for  $\phi^*$ :

$$\phi^* = \mathbf{1} - (\mathbf{1} - \mathbf{p}\phi^*)^T.$$

Look for critical infection probability p<sub>c</sub>.
As φ<sup>\*</sup> → 0, we see

 $\phi^* \simeq \rho T \phi^* \Rightarrow \rho_c = 1/T.$ 

- Again find continuous phase transition...
- Note: we can solve for p but not  $\phi^*$ :

$$p = (\phi^*)^{-1} [1 - (1 - \phi^*)^{1/T}].$$

Generalized

Contagion

ntroduction

ndependent Interaction models

nteraction mode

Generalized Mod

# Homogeneous, one hit models: Fixed points for r < 1, $d^* = 1$ , and T > 1

► In general, relevant dose histories are:

$$H_{m+1} = \{\ldots, d_{t-T-m-1}, 1, \underbrace{0, 0, \ldots, 0, 0}_{m \ 0's}, \underbrace{0, 0, \ldots, 0, 0}_{T \ 0's}\}.$$

Overall probabilities for dose histories occurring:

$$P(H_1) = p\phi^*(1 - p\phi^*)^T(1 - r),$$

$$P(H_{m+1}) = \underbrace{p\phi^*}_{a} \underbrace{(1-p\phi^*)^{T+m}}_{b} \underbrace{(1-r)^{m+1}}_{c}.$$

a: Pr(infection T + m + 1 time steps ago)
b: Pr(no doses received in T + m time steps since)
c: Pr(no recovery in m chances)

nteraction model

Generalized Mode

Generalized

Contagion

# Homogeneous, one hit models:

Fixed points for  $r \leq 1$ ,  $d^* = 1$ , and  $T \geq 1$ 

Pr(recovery) = Pr(seeing no doses for at least T time steps and recovering)

$$= r \sum_{m=0}^{\infty} P(H_{T+m}) = r \sum_{m=0}^{\infty} p \phi^* (1 - p \phi^*)^{T+m} (1 - r)^m$$
$$= r \frac{p \phi^* (1 - p \phi^*)^T}{1 - (1 - p \phi^*)(1 - r)}.$$

Fixed point equation:

$$\phi^* = 1 - \frac{r(1 - p\phi^*)^T}{1 - (1 - p\phi^*)(1 - r)}$$

Fixed points for 
$$d^* = 1, r \le 1$$
, and  $T \ge 1$   
•  $\phi^* = 1 - \frac{r(1-p\phi^*)^T}{1-(1-p\phi^*)(1-r)}$   
•  $\phi^* = 0$   
•  $p_c = 1/(T + \tau)$   
•  $\phi^* = 0/2$   
•  $p_c = 1/(T + \tau)$ 

- Example details:  $T = 2 \& r = 1/2 \Rightarrow p_c = 1/3$ .
- Blue = stable, red = unstable, fixed points.
- $\tau = 1/r 1$  = characteristic recovery time = 1.
- $T + \tau \simeq$  average memory in system = 3.
- Phase transition can be seen as a transcritical bifurcation.<sup>[11]</sup>

eferences

# Fixed points for r < 1, $d^* > 1$ , and $T \ge 1$

- For r < 1, need to determine probability of recovering as a function of time since dose load last dropped below threshold.
- Partially summed random walks:

$$D_i(t) = \sum_{t'=t-T+1}^t d_i(t')$$

• Example for T = 24,  $d^* = 14$ :

# Fixed points for r < 1, $d^* > 1$ , and $T \ge 1$ Example: T = 3, $d^* = 2$

Want to examine how dose load can drop below threshold of d\* = 2:

$$D_n = 2 \Rightarrow D_{n+1} = 1$$

• Two subsequences do this:  $\{d_{n-2}, d_{n-1}, d_n, d_{n+1}\} = \{1, 1, 0, 0\}$ 

and  $\{d_{n-2}, d_{n-1}, d_n, d_{n+1}, d_{n+2}\} = \{1, 0, 1, 0, 0\}.$ 

- Note: second sequence includes an extra 0 since this is necessary to stay below d\* = 2.
- To stay below threshold, observe acceptable following sequences may be composed of any combination of two subsequences:

 $a = \{0\}$  and  $b = \{1, 0, 0\}.$ 

Frame 37/63

# Generalized model—heterogeneity, r = 1Fixed point equation:

$$\phi^* = \sum_{k=1}^T \binom{T}{k} (\boldsymbol{p}\phi^*)^k (1 - \boldsymbol{p}\phi^*)^{T-k} \underline{\boldsymbol{P}_k}$$

• Expand around  $\phi^* = 0$  to find when spread from single seed is possible:

> $\Rightarrow p_c = 1/(TP_1)$  $pP_1T \geq 1$ or

- Very good:
  - 1.  $P_1T$  is the expected number of vulnerables the initial infected individual meets before recovering.
  - 2.  $pP_1T$  is  $\therefore$  the expected number of successful infections (equivalent to  $R_0$ ).
- Observe:  $p_c$  may exceed 1 meaning no spreading from a small seed.

# Heterogeneous case

# Example configuration:

- Dose sizes are lognormally distributed with mean 1 and variance 0.433.
- Memory span: T = 10.
- Thresholds are uniformly set at
  - 1.  $d_* = 0.5$
  - 2.  $d_* = 1.6$
  - 3.  $d_* = 3$
- Spread of dose sizes matters, details are not important.

# Heterogeneous case

- Next: Determine slope of fixed point curve at critical point  $p_c$ .
- Expand fixed point equation around  $(p, \phi^*) = (p_c, 0)$ .
- Find slope depends on  $(P_1 P_2/2)^{[5]}$ (see appendix).
- Behavior near fixed point depends on whether this slope is
  - 1. positive:  $P_1 > P_2/2$  (continuous phase transition)
  - 2. negative:  $P_1 < P_2/2$  (discontinuous phase transition)
- Now find three basic universal classes of contagion models...

# Heterogeneous case

- II-III transition generalizes:  $p_c = 1/[P_1(T + \tau)]$  where  $\tau = 1/r$  = expected recovery time
- I-II transition less pleasant analytically.

# Discussion

- Memory is a natural ingredient.
- Three universal classes of contagion processes:
  - 1. I. Epidemic Threshold
  - 2. II. Vanishing Critical Mass
  - 3. III. Critical Mass
- Dramatic changes in behavior possible.
- To change kind of model: 'adjust' memory, recovery, fraction of vulnerable individuals (*T*, *r*, *ρ*, *P*<sub>1</sub>, and/or *P*<sub>2</sub>).
- To change behavior given model: 'adjust' probability of exposure (p) and/or initial number infected (\u03c6<sub>0</sub>).

Frame 55/63

# Discussion

- Single seed infects others if  $pP_1(T + \tau) \ge 1$ .
- Key quantity:  $p_c = 1/[P_1(T + \tau)]$
- If  $p_c < 1 \Rightarrow$  contagion can spread from single seed.
- Depends only on:
  - 1. 1. System Memory  $(T + \tau)$ .
  - 2. 2. Fraction of highly vulnerable individuals  $(P_1)$ .
- Details unimportant: Many threshold and dose distributions give same P<sub>k</sub>.
- Most vulnerable/gullible population may be more important than small group of super-spreaders or influentials.

# Details for Class I-II transition:

$$C_m = (-1)^m \binom{T}{m} \sum_{k=1}^m (-1)^k \binom{m}{k} P_k,$$

since

$$\binom{T}{k} \binom{T-k}{m-k} = \frac{T!}{k!(T-k)!} \frac{(T-k)!}{(m-k)!(T-l)!}$$

$$= \frac{T!}{m!(T-m)!} \frac{m!}{k!(l-k)!}$$

$$= \binom{T}{m} \binom{m}{k}.$$

# Details for Class I-II transition:

$$\begin{split} \phi^* &= \sum_{k=1}^T \binom{T}{k} P_k (p\phi^*)^k (1 - p\phi^*)^{T-k}, \\ &= \sum_{k=1}^T \binom{T}{k} P_k (p\phi^*)^k \sum_{j=0}^{T-k} \binom{T-k}{j} (-p\phi^*)^j, \\ &= \sum_{k=1}^T \sum_{j=0}^{T-k} \binom{T}{k} \binom{T-k}{j} P_k (-1)^j (p\phi^*)^{k+j}, \\ &= \sum_{l=1}^T \sum_{k=1}^m \binom{T}{k} \binom{T-k}{m-k} P_k (-1)^{m-k} (p\phi^*)^m, \\ &= \sum_{m=1}^T C_m (p\phi^*)^m \end{split}$$

Details for Class I-II transition:

Linearization gives

 $\phi^* \simeq C_1 \rho \phi^* + C_2 \rho_c^2 \phi^{*2}.$ 

where  $C_1 = TP_1(=1/p_c)$  and  $C_2 = {T \choose 2}(-2P_1 + P_2)$ . • Using  $p_c = 1/(TP_1)$ :

$$\phi^* \simeq rac{C_1}{C_2 \rho_c^2} (\rho - \rho_c) = rac{T^2 P_1^3}{(T-1)(P_1 - P_2/2)} (\rho - \rho_c).$$

Sign of derivative governed by  $P_1 - P_2/2$ .
