# Hierarchy by division

## Bottom up:

- ▶ **Idea:** Extract hierarchical classification scheme for  $N$  objects by an agglomeration process.
- ▶ Need a measure of distance between all pairs of objects.
- ▶ Note: evidently works for non-networked data.
- ▶ **Procedure:**
  1. Order pair-based distances.
  2. Sequentially add links between nodes based on closeness.
  3. Use additional criteria to determine when clusters are meaningful.
- ▶ Clusters gradually emerge, likely with clusters inside of clusters.
- ▶ Call above property **Modularity**.

# Hierarchy by division

## Bottom up problems:

- ▶ Tend to plainly not work on data sets with known modular structures.
- ▶ Good at finding cores of well-connected (or similar) nodes...  
but fail to cope well with peripheral, in-between nodes.

# Hierarchy by division

## Top down:

- ▶ **Idea:** Identify **global structure first** and recursively uncover more detailed structure.
- ▶ **Basic objective:** find dominant components that have significantly more links within than without, as compared to randomized version.
- ▶ We'll first work through "Finding and evaluating community structure in networks" by Newman and Girvan (PRE, 2004). [7]
- ▶ See also
  1. "Scientific collaboration networks. II. Shortest paths, weighted networks, and centrality" by Newman (PRE, 2001). [5, 6]
  2. "Community structure in social and biological networks" by Girvan and Newman (PNAS, 2002). [3]

# Hierarchy by division

- ▶ *Idea:*  
Edges that **connect** communities have **higher betweenness** than edges **within** communities.

# Hierarchy by division

## One class of structure-detection algorithms:

1. Compute edge betweenness for whole network.
2. Remove edge with highest betweenness.
3. Recompute edge betweenness
4. Repeat steps 2 and 3 until all edges are removed.
5. Record when components appear as a function of # edges removed.
6. Generate dendrogram revealing hierarchical structure.

# Hierarchy by division

## Key element:

- ▶ **Recomputing betweenness.**
- ▶ **Reason:** Possible to have a low betweenness in links that connect large communities if other links carry majority of shortest paths.

## When to stop?:

- ▶ How do we know which divisions are meaningful?
- ▶ **Modularity measure:** difference in fraction of within component nodes to that expected for randomized version:

$$Q = \frac{1}{2m} \sum_i \sum_j \left( A_{ij} - \frac{k_i k_j}{2m} \right) \delta_{ij}^c$$

where  $\delta_{ij}^c$  is the fraction of edges between community  $c$  and  $j$ .

# Hierarchies and missing links

- ▶ Model also predicts reasonably well
  1. average degree,
  2. clustering,
  3. and average shortest path length.

**Table 1 | Comparison of original and resampled networks**

Network	$\langle k \rangle_{\text{real}}$	$\langle k \rangle_{\text{samp}}$	$C_{\text{real}}$	$C_{\text{samp}}$	$d_{\text{real}}$	$d_{\text{samp}}$
<i>T. pallidum</i>	4.8	3.7(1)	0.0625	0.0444(2)	3.690	3.940(6)
Terrorists	4.9	5.1(2)	0.361	0.352(1)	2.575	2.794(7)
Grassland	3.0	2.9(1)	0.174	0.168(1)	3.29	3.69(2)

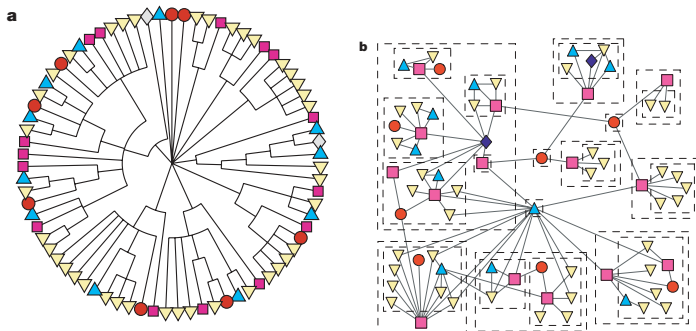

Statistics are shown for the three example networks studied and for new networks generated by resampling from our hierarchical model. The generated networks closely match the average degree  $\langle k \rangle$ , clustering coefficient  $C$  and average vertex-vertex distance  $d$  in each case, suggesting that they capture much of the structure of the real networks. Parenthetical values indicate standard errors on the final digits.
