In x is distributed according to a normal distribution with mean μ and variance σ .

► Appears in economics and biology where growth increments are distributed normally.

 $P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$

lognormals

lognormals

The lognormal distribution:

▶ Standard form reveals the mean μ and variance σ^2 of the underlying normal distribution:

$$P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

For lognormals:

$$\mu_{ ext{lognormal}} = oldsymbol{e}^{\mu + rac{1}{2}\sigma^2}, \qquad ext{median}_{ ext{lognormal}} = oldsymbol{e}^{\mu},$$

$$\sigma_{ ext{lognormal}} = (e^{\sigma^2} - 1)e^{2\mu + \sigma^2}, \qquad ext{mode}_{ ext{lognormal}} = e^{\mu - \sigma^2}$$

All moments of lognormals are finite.

Alternative distributions

There are other 'heavy-tailed' distributions:

1. The Log-normal distribution (⊞)

$$P(x) = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right)$$

2. Weibull distributions (⊞)

$$P(x)dx = \frac{k}{\lambda} \left(\frac{x}{\lambda}\right)^{\mu-1} e^{-(x/\lambda)^{\mu}} dx$$

CCDF = stretched exponential (⊞).

3. Gamma distributions (⊞), and more.

Lognormals and friends

Derivation from a normal distribution

Take Y as distributed normally:

 $P(y)dy = \frac{1}{\sqrt{2\pi}\sigma}dy \exp\left(-\frac{(y-\mu)^2}{2\sigma^2}\right)$

Set $Y = \ln X$:

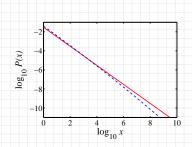

▶ Transform according to P(x)dx = P(y)dy:

 $\frac{\mathrm{d}y}{\mathrm{d}x} = 1/x \Rightarrow \mathrm{d}y = \mathrm{d}x/x$

$$\Rightarrow P(x)dx = \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) dx$$

Confusion between lognormals and pure power laws

Near agreement over four orders of magnitude!

- For lognormal (blue), $\mu = 0$ and $\sigma = 10$.
- For power law (red), $\gamma = 1$ and c = 0.03.

UNIVERSITY VERMONT 少 Q (~ 8 of 23

Generating lognormals:

Random multiplicative growth:

$$x_{n+1} = rx_n$$

where r > 0 is a random growth variable

- (Shrinkage is allowed)
- In log space, growth is by addition:

$$\ln x_{n+1} = \ln r + \ln x_n$$

- \Rightarrow ln x_n is normally distributed
- $\Rightarrow x_n$ is lognormally distributed

Confusion

What's happening:

$$\ln P(x) = \ln \left\{ \frac{1}{x\sqrt{2\pi}\sigma} \exp\left(-\frac{(\ln x - \mu)^2}{2\sigma^2}\right) \right\}$$

$$=-\ln x-\ln \sqrt{2\pi}-\frac{(\ln x-\mu)^2}{2\sigma^2}$$

 $= -\frac{1}{2\sigma^2} (\ln x)^2 + \left(\frac{\mu}{\sigma^2} - 1\right) \ln x - \ln \sqrt{2\pi} - \frac{\mu^2}{2\sigma^2}$

▶ \Rightarrow If $\sigma^2 \gg 1$ and μ ,

 $\ln P(x) \sim -\ln x + \text{const.}$

Lognormals or power laws?

- ► Gibrat [2] (1931) uses preceding argument to explain lognormal distribution of firm sizes ($\gamma \simeq 1$).
- But Robert Axtell [1] (2001) shows a power law fits the data very well with $\gamma = 2$, not $\gamma = 1$ (!)
- Problem of data censusing (missing small firms).

 One mechanistic piece in Gibrat's model seems okay empirically: Growth rate r appears to be independent of firm size. [1].

Confusion

- Expect -1 scaling to hold until (ln x)² term becomes significant compared to $(\ln x)$.
- This happens when (roughly)

$$-\frac{1}{2\sigma^2}(\ln x)^2 \simeq 0.05 \left(\frac{\mu}{\sigma^2} - 1\right) \ln x$$

 $\Rightarrow \log_{10} x \lesssim 0.05 \times 2(\sigma^2 - \mu) \log_{10} e$

$$\simeq 0.05 (\sigma^2 - \mu)$$

→ If you find a -1 exponent, you may have a lognormal distribution...

Lognormals and

UNIVERSITY OF VERMONT 夕 Q № 10 of 23

An explanation

- Axtel (mis?)cites Malcai et al.'s (1999) argument [5] for why power laws appear with exponent $\gamma \simeq 1$
- ▶ The set up: N entities with size $x_i(t)$
- Generally:

$$x_i(t+1)=rx_i(t)$$

where r is drawn from some happy distribution

- Same as for lognormal but one extra piece.
- Each x_i cannot drop too low with respect to the other sizes:

$$x_i(t+1) = \max(rx_i(t), c\langle x_i\rangle)$$

An explanation

Some math later... Insert question from assignment 6 (⊞)

Find
$$P(x) \sim x^{-\gamma}$$

 \blacktriangleright where γ is implicitly given by

$$N = \frac{(\gamma - 2)}{(\gamma - 1)} \left[\frac{(c/N)^{\gamma - 1} - 1}{(c/N)^{\gamma - 1} - (c/N)} \right]$$

N = total number of firms.

Now, if $c/N \ll 1$, $N = \frac{(\gamma - 2)}{(\gamma - 1)} \begin{bmatrix} -1 \\ -(c/N) \end{bmatrix}$

Which gives $\gamma \sim 1 + \frac{1}{1-c}$

▶ Groovy... c small $\Rightarrow \gamma \simeq 2$

References

The second tweak

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda(\ln x/m)^2}}$$

▶ Depends on sign of $\ln x/m$, i.e., whether x/m > 1 or x/m < 1.

$$P(x) \propto \begin{cases} x^{-1+\sqrt{2\lambda}} & \text{if } x/m < 1\\ x^{-1-\sqrt{2\lambda}} & \text{if } x/m > 1 \end{cases}$$

- 'Break' in scaling (not uncommon)
- ▶ Double-Pareto distribution (⊞)
- First noticed by Montroll and Shlesinger [7, 8]
- ► Later: Huberman and Adamic [3, 4]: Number of pages per website

Random Growth with Variable Lifespar

UNIVERSITY OF VERMONT

夕 Q № 19 of 23

The second tweak

Ages of firms/people/... may not be the same

- \blacktriangleright Allow the number of updates for each size x_i to vary
- ► Example: $P(t)dt = ae^{-at}dt$ where t = age.
- ▶ Back to no bottom limit: each x_i follows a lognormal
- ► Sizes are distributed as [6]

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln x - \mu)^2}{2t}\right) dt$$

(Assume for this example that $\sigma \sim t$ and $\mu = \ln m$)

Now averaging different lognormal distributions.

Summary of these exciting developments:

- Lognormals and power laws can be awfully similar
- Random Multiplicative Growth leads to lognormal distributions
- Enforcing a minimum size leads to a power law tail
- With no minimum size but a distribution of lifetimes, the double Pareto distribution appears
- Take-home message: Be careful out there...

Averaging lognormals

$$P(x) = \int_{t=0}^{\infty} ae^{-at} \frac{1}{x\sqrt{2\pi t}} \exp\left(-\frac{(\ln x/m)^2}{2t}\right) dt$$

- ► Insert question from assignment 6 (⊞)
- Some enjoyable suffering leads to:

$$P(x) \propto x^{-1} e^{-\sqrt{2\lambda(\ln x/m)^2}}$$
