net•work |'netwərk|

noun

1 an arrangement of intersecting horizontal and vertical lines.

- a complex system of roads, railroads, or other transportation routes : *a network of railroads.*

2 a group or system of interconnected people or things : *a trade network.*

- a group of people who exchange information, contacts, and experience for professional or social purposes : *a support network.*
- a group of broadcasting stations that connect for the simultaneous broadcast of a program : *the introduction of a second TV network* | [as adj.] *network television.*
- a number of interconnected computers, machines, or operations : *specialized computers that manage multiple outside connections to a network* | *a local cellular phone network.*
- a system of connected electrical conductors.

verb [trans.]

connect as or operate with a network : *the stock exchanges have proven to be resourceful in networking these deals.*

- link (machines, esp. computers) to operate interactively : [as adj.] (**networked**) *networked workstations.*
- [intrans.] [often as n.] (**networking**) interact with other people to exchange information and develop contacts, esp. to further one's career : *the skills of networking, bargaining, and negotiation.*

Thesaurus deliciousness:

network

noun

- 1** *a network of arteries* WEB, lattice, net, matrix, mesh, crisscross, grid, reticulum, reticulation; Anatomy plexus.
- 2** *a network of lanes* MAZE, labyrinth, warren, tangle.
- 3** *a network of friends* SYSTEM, complex, nexus, web, webwork.

Net and Work are venerable old words:

- ▶ 'Net' first used to mean spider web (King Ælfréd, 888).
- ▶ 'Work' appear to have long meant purposeful action.

The network of Germanic 'net' words

The network of 'work' words

- ▶ 'Network' = something built based on the idea of natural, flexible lattice or web.
- ▶ c.f., ironwork, stonework, fretwork.

Key Observation:

- ▶ Many **complex systems** can be viewed as **complex networks** of physical or abstract interactions.
- ▶ Opens door to mathematical and numerical analysis.
- ▶ Dominant approach of last decade of a **theoretical-physics/stat-mechish** flavor.
- ▶ Mindboggling amount of work published on complex networks since 1998...
- ▶ ... largely due to your typical theoretical physicist:

- ▶ *Piranha physicus*
- ▶ Hunt in packs.
- ▶ Feast on new and interesting ideas (see chaos, cellular automata, ...)

Popularity (according to ISI)

“Collective dynamics of ‘small-world’ networks” [30]

- ▶ Watts and Strogatz
Nature, 1998
- ▶ Cited ≈ 4325 times (as of June 7, 2010)
- ▶ Over 1100 citations in 2008 alone.

“Emergence of scaling in random networks” [4]

- ▶ Barabási and Albert
Science, 1999
- ▶ Cited ≈ 4769 times (as of June 7, 2010)
- ▶ Over 1100 citations in 2008 alone.

Super Basic definitions

Nodes = A collection of entities which have properties that are somehow related to each other

- ▶ e.g., people, forks in rivers, proteins, webpages, organisms,...

Links = Connections between nodes

- ▶ **Links** may be directed or undirected.
- ▶ **Links** may be binary or weighted.

Other spiffing words: vertices and edges.

Super Basic definitions

Node degree = Number of links per node

- ▶ Notation: Node i 's degree = k_i .
- ▶ $k_i = 0, 1, 2, \dots$
- ▶ Notation: the average degree of a network = $\langle k \rangle$ (and sometimes z)
- ▶ Connection between number of edges m and average degree:

$$\langle k \rangle = \frac{2m}{N}.$$

- ▶ Defn: \mathcal{N}_i = the set of i 's k_i neighbors

Super Basic definitions

Adjacency matrix:

- ▶ We represent a directed network by a matrix A with link weight a_{ij} for nodes i and j in entry (i, j) .
- ▶ e.g.,

$$A = \begin{bmatrix} 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \end{bmatrix}$$

- ▶ (n.b., for numerical work, we always use sparse matrices.)

So what passes for a complex network?

- ▶ Complex networks are **large** (in node number)
- ▶ Complex networks are **sparse** (low edge to node ratio)
- ▶ Complex networks are usually **dynamic** and **evolving**
- ▶ Complex networks can be social, economic, natural, informational, abstract, ...

Examples

Physical networks

- ▶ River networks
- ▶ Neural networks
- ▶ Trees and leaves
- ▶ Blood networks
- ▶ The Internet
- ▶ Road networks
- ▶ Power grids

- ▶ **Distribution** (branching) versus **redistribution** (cyclical)

A notable feature of large-scale networks:

- ▶ Graphical renderings are often just a big mess.

⇐ Typical hairball

- ▶ number of nodes $N = 500$
 - ▶ number of edges $m = 1000$
 - ▶ average degree $\langle k \rangle = 4$
- ▶ And even when renderings somehow look good:
“That is a very graphic analogy which aids understanding wonderfully while being, strictly speaking, wrong in every possible way”
said Ponder [Stibbons] —*Making Money*, T. Pratchett.
- ▶ We need to extract **digestible, meaningful aspects**.

Properties

Some key features of real complex networks:

- ▶ Degree distribution
 - ▶ Assortativity
 - ▶ Homophily
 - ▶ Clustering
 - ▶ Motifs
 - ▶ Modularity
 - ▶ Concurrency
 - ▶ Hierarchical scaling
 - ▶ Network distances
 - ▶ Centrality
 - ▶ Efficiency
 - ▶ Robustness
- ▶ Coevolution of network **structure** and **processes** on networks.

1. Degree distribution P_k

- ▶ P_k is the probability that a randomly selected node has degree k
- ▶ **Big deal:** Form of P_k key to network's behavior
- ▶ **ex 1:** Erdős-Rényi random networks have a Poisson distribution:

$$P_k = e^{-\langle k \rangle} \langle k \rangle^k / k!$$

- ▶ **ex 2:** “Scale-free” networks: $P_k \propto k^{-\gamma} \Rightarrow$ ‘hubs’
- ▶ We'll come back to this business soon...

2. Assortativity/3. Homophily:

- ▶ Social networks: Homophily (☐) = birds of a feather
- ▶ e.g., degree is standard property for sorting: measure degree-degree correlations.
- ▶ **Assortative** network: ^[20] similar degree nodes connecting to each other.
 - ▶ Often *social*: company directors, coauthors, actors.
- ▶ **Disassortative** network: high degree nodes connecting to low degree nodes.
 - ▶ Often *technological* or *biological*: Internet, protein interactions, neural networks, food webs.

4. Clustering:

- ▶ Your friends tend to know each other.
- ▶ Two measures:

$$C_1 = \left\langle \frac{\sum_{j_1 j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i(k_i - 1)/2} \right\rangle_i \text{ due to Watts \& Strogatz [30]}$$

$$C_2 = \frac{3 \times \# \text{triangles}}{\# \text{triples}} \text{ due to Newman [21]}$$

- ▶ C_1 is the **average fraction** of **pairs of neighbors** who are **connected**.
- ▶ Interpret C_2 as probability two of a node's friends know each other.

5. Motifs:

- ▶ Small, recurring functional subnetworks
- ▶ e.g., Feed Forward Loop:

Shen-Orr, Uri Alon, *et al.* [23]

Properties

6. modularity:

Clauset *et al.*, 2006 ^[10]: NCAA football

networks

References

7. Concurrency:

- ▶ Transmission of a contagious element only occurs during contact^[18]
- ▶ Rather obvious but easily missed in a simple model
- ▶ Dynamic property—static networks are not enough
- ▶ Knowledge of previous contacts crucial
- ▶ **Beware** cumulated network data!

Properties

8. Horton-Strahler stream ordering:

- ▶ Metrics for branching networks:
 - ▶ Method for ordering streams hierarchically
 - ▶ Reveals fractal nature of natural branching networks
 - ▶ Hierarchy is not pure but mixed (Tokunaga). [25, 12]
 - ▶ Major examples: rivers and blood networks.

- ▶ Beautifully described but poorly explained.

9. Network distances:

(a) shortest path length d_{ij} :

- ▶ Fewest number of steps between nodes i and j .
- ▶ (Also called the chemical distance between i and j .)

(b) average path length $\langle d_{ij} \rangle$:

- ▶ Average shortest path length in whole network.
- ▶ Good algorithms exist for calculation.
- ▶ Weighted links can be accommodated.

9. Network distances:

(c) Network diameter d_{\max} :

- ▶ Maximum shortest path length in network.

(d) Closeness $d_{cl} = [\sum_{ij} d_{ij}^{-1} / \binom{n}{2}]^{-1}$:

- ▶ Average 'distance' between any two nodes.
- ▶ Closeness handles disconnected networks ($d_{ij} = \infty$)
- ▶ $d_{cl} = \infty$ only when all nodes are isolated.

10. Centrality:

- ▶ Many such measures of a node's 'importance.'
- ▶ **ex 1:** Degree centrality: k_i .
- ▶ **ex 2:** Node i 's betweenness
= fraction of shortest paths that pass through i .
- ▶ **ex 3:** Edge ℓ 's betweenness
= fraction of shortest paths that travel along ℓ .
- ▶ **ex 4:** Recursive centrality: Hubs and Authorities (Jon Kleinberg^[17])

Overview Key Points:

- ▶ The field of complex networks came into existence in the late 1990s.
- ▶ Explosion of papers and interest since 1998/99.
- ▶ Hardened up much thinking about complex systems.
- ▶ Specific focus on networks that are **large-scale**, **sparse**, **natural** or **man-made**, **evolving** and **dynamic**, and (crucially) **measurable**.
- ▶ Three main (blurred) categories:
 1. **Physical** (e.g., river networks),
 2. **Interactional** (e.g., social networks),
 3. **Abstract** (e.g., thesauri).

Nutshell

Overview Key Points (cont.):

- ▶ Obvious connections with the vast extant field of graph theory.
- ▶ But focus on dynamics is more of a physics/stat-mech/comp-sci flavor.
- ▶ Two main areas of focus:
 1. **Description:** Characterizing very large networks
 2. **Explanation:** Micro story \Rightarrow Macro features
- ▶ Some essential structural aspects are understood: degree distribution, clustering, assortativity, group structure, overall structure,...
- ▶ Still much work to be done, especially with respect to dynamics...

Some important models:

1. generalized random networks
2. scale-free networks
3. small-world networks
4. statistical generative models (p^*)
5. generalized affiliation networks

Generalized random networks:

- ▶ Arbitrary degree distribution P_k .
- ▶ Create (unconnected) nodes with degrees sampled from P_k .
- ▶ Wire nodes together randomly.
- ▶ Create ensemble to test deviations from randomness.

Building random networks: Stubs

Phase 1:

- ▶ **Idea:** start with a soup of unconnected nodes with **stubs** (half-edges):

- ▶ Randomly select stubs (not nodes!) and connect them.
- ▶ Must have an even number of stubs.
- ▶ Initially allow **self-** and **repeat** connections.

Building random networks: First rewiring

Phase 2:

- ▶ Now find any (A) self-loops and (B) repeat edges and **randomly rewire** them.

- ▶ **Being careful:** we can't change the degree of any node, so we can't simply move links around.
- ▶ **Simplest solution:** randomly rewire **two edges** at a time.

General random rewiring algorithm

- ▶ Randomly choose **two edges**. (Or choose problem edge and a random edge)
- ▶ Check to make sure edges are **disjoint**.
- ▶ Rewire one end of each edge.
- ▶ Node degrees **do not change**.
- ▶ Works if e_1 is a self-loop or repeated edge.
- ▶ Same as finding on/off/on/off 4-cycles. and rotating them.

Sampling random networks

Phase 2:

- ▶ Use rewiring algorithm to remove all self and repeat loops.

Phase 3:

- ▶ **Randomize network** wiring by applying rewiring algorithm liberally.
- ▶ **Rule of thumb:** # Rewirings $\simeq 10 \times$ # edges^[19].

References

Scale-free networks

- ▶ Networks with power-law degree distributions have become known as **scale-free** networks.
- ▶ Scale-free refers specifically to the **degree distribution** having a **power-law decay** in its tail:

$$P_k \sim k^{-\gamma} \text{ for 'large' } k$$

- ▶ One of the seminal works in complex networks: Laszlo Barabási and Reka Albert, Science, 1999: “Emergence of scaling in random networks” [4]
- ▶ Somewhat misleading nomenclature...

Scale-free networks

- ▶ Scale-free networks are **not fractal** in any sense.
- ▶ Usually talking about networks whose links are **abstract, relational, informational**, . . . (non-physical)
- ▶ Primary example: hyperlink network of the Web
- ▶ Much arguing about whether or networks are 'scale-free' or not. . .

Scale-free networks

The big deal:

- ▶ We move beyond describing networks to finding **mechanisms** for why certain networks are the way they are.

A big deal for scale-free networks:

- ▶ How does the exponent γ depend on the mechanism?
- ▶ Do the mechanism details matter?

BA model

- ▶ Barabási-Albert model = BA model.
- ▶ Key ingredients:
Growth and **Preferential Attachment (PA)**.
- ▶ **Step 1**: start with m_0 disconnected nodes.
- ▶ **Step 2**:
 1. **Growth**—a new node appears at each time step $t = 0, 1, 2, \dots$
 2. Each new node makes m links to nodes already present.
 3. **Preferential attachment**—Probability of connecting to i th node is $\propto k_i$.
- ▶ In essence, we have a **rich-gets-richer** scheme.

BA model

- ▶ **Definition:** A_k is the **attachment kernel** for a node with degree k .
- ▶ For the original model:

$$A_k = k$$

- ▶ **Definition:** $P_{\text{attach}}(k, t)$ is the attachment probability.
- ▶ For the original model:

$$P_{\text{attach}}(\text{node } i, t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{\max}(t)} k N_k(t)}$$

where $N(t) = m_0 + t$ is # nodes at time t
and $N_k(t)$ is # degree k nodes at time t .

Approximate analysis

- ▶ When $(N + 1)$ th node is added, the expected increase in the degree of node i is

$$E(k_{i,N+1} - k_{i,N}) \simeq m \frac{k_{i,N}}{\sum_{j=1}^{N(t)} k_j(t)}.$$

- ▶ Assumes probability of being connected to is **small**.
- ▶ Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.
- ▶ Approximate $k_{i,N+1} - k_{i,N}$ with $\frac{d}{dt}k_{i,t}$:

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where $t = N(t) - m_0$.

Approximate analysis

- Deal with denominator: each added node brings m new edges.

$$\therefore \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

- The node degree equation now simplifies:

$$\frac{d}{dt} k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = m \frac{k_i(t)}{2mt} = \frac{1}{2t} k_i(t)$$

- Rearrange and solve:

$$\frac{dk_i(t)}{k_i(t)} = \frac{dt}{2t} \Rightarrow k_i(t) = c_i t^{1/2}.$$

- Next find $c_i \dots$

Approximate analysis

- ▶ Know i th node appears at time

$$t_{i,\text{start}} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

- ▶ So for $i > m_0$ (exclude initial nodes), we must have

$$k_i(t) = m \left(\frac{t}{t_{i,\text{start}}} \right)^{1/2} \quad \text{for } t \geq t_{i,\text{start}}.$$

- ▶ All node degrees grow as $t^{1/2}$ but later nodes have larger $t_{i,\text{start}}$ which **flattens out** growth curve.
- ▶ Early nodes do **best** (First-mover advantage).

Approximate analysis

- ▶ $m = 3$
- ▶ $t_{i,\text{start}} = 1, 2, 5, \text{ and } 10.$

Degree distribution

- ▶ So what's the **degree distribution** at time t ?
- ▶ Use fact that birth time for added nodes is distributed uniformly:

$$\Pr(t_{i,\text{start}}) dt_{i,\text{start}} \simeq \frac{dt_{i,\text{start}}}{t}$$

- ▶ Also use

$$k_i(t) = m \left(\frac{t}{t_{i,\text{start}}} \right)^{1/2} \Rightarrow t_{i,\text{start}} = \frac{m^2 t}{k_i(t)^2}.$$

Transform variables—Jacobian:

$$\frac{dt_{i,\text{start}}}{dk_i} = -2 \frac{m^2 t}{k_i(t)^3}.$$

Degree distribution

$$\Pr(k_i)dk_i = \Pr(t_{i,\text{start}})dt_{i,\text{start}}$$

$$= \Pr(t_{i,\text{start}})dk_i \left| \frac{dt_{i,\text{start}}}{dk_i} \right|$$

$$= \frac{1}{t} dk_i 2 \frac{m^2 t}{k_i(t)^3}$$

$$= 2 \frac{m^2}{k_i(t)^3} dk_i$$

$$\propto k_i^{-3} dk_i.$$

Degree distribution

- ▶ We thus have a very specific prediction of $\Pr(k) \sim k^{-\gamma}$ with $\gamma = 3$.
- ▶ Typical for real networks: $2 < \gamma < 3$.
- ▶ Range true more generally for events with size distributions that have power-law tails.
- ▶ $2 < \gamma < 3$: finite mean and 'infinite' variance (wild)
- ▶ In practice, $\gamma < 3$ means variance is governed by upper cutoff.
- ▶ $\gamma > 3$: finite mean and variance (mild)

Examples

WWW	$\gamma \simeq 2.1$ for in-degree
WWW	$\gamma \simeq 2.45$ for out-degree
Movie actors	$\gamma \simeq 2.3$
Words (synonyms)	$\gamma \simeq 2.8$

The Internet's is a different business...

Real data

From Barabási and Albert's original paper [4]:

Fig. 1. The distribution function of connectivities for various large networks. **(A)** Actor collaboration graph with $N = 212,250$ vertices and average connectivity $\langle k \rangle = 28.78$. **(B)** WWW, $N = 325,729$, $\langle k \rangle = 5.46$. **(C)** Power grid data, $N = 4941$, $\langle k \rangle = 2.67$. The dashed lines have slopes **(A)** $\gamma_{actor} = 2.3$, **(B)** $\gamma_{www} = 2.1$ and **(C)** $\gamma_{power} = 4$.

Things to do and questions

- ▶ Vary attachment kernel.
- ▶ Vary mechanisms:
 1. Add edge deletion
 2. Add node deletion
 3. Add edge rewiring
- ▶ Deal with directed versus undirected networks.
- ▶ **Important Q.:** Are there distinct universality classes for these networks?
- ▶ **Q.:** How does changing the model affect γ ?
- ▶ **Q.:** Do we need preferential attachment and growth?
- ▶ **Q.:** Do model details matter?
- ▶ The answer is (surprisingly) **yes**. More later re Zipf.

Preferential attachment

- ▶ Let's look at preferential attachment (PA) a little more closely.
- ▶ PA implies arriving nodes have **complete knowledge** of the existing network's degree distribution.
- ▶ For example: If $P_{\text{attach}}(k) \propto k$, we need to determine the constant of proportionality.
- ▶ We need to know what everyone's degree is...
- ▶ PA is \therefore an **outrageous** assumption of node capability.
- ▶ But a **very simple mechanism** saves the day...

Preferential attachment through randomness

- ▶ Instead of attaching preferentially, allow new nodes to attach randomly.
- ▶ Now add an **extra step**: new nodes then connect to some of their friends' friends.
- ▶ Can also do this **at random**.
- ▶ Assuming the existing network is random, we know probability of a **random friend** having degree k is

$$Q_k \propto kP_k$$

- ▶ So **rich-gets-richer** scheme can now be seen to work in a natural way.

Robustness

- ▶ **System robustness** and system robustness.
- ▶ Albert et al., Nature, 2000:
“Error and attack tolerance of complex networks” [3]

Robustness

- ▶ Scale-free networks are thus **robust to random failures** yet **fragile to targeted ones**.
- ▶ All very reasonable: **Hubs** are a big deal.
- ▶ **But:** next issue is whether hubs are vulnerable or not.
- ▶ Representing all webpages as the same size node is obviously a stretch (e.g., google vs. a random person's webpage)
- ▶ Most connected nodes are either:
 1. Physically larger nodes that may be harder to 'target'
 2. or subnetworks of smaller, normal-sized nodes.
- ▶ Need to explore cost of various targeting schemes.

People thinking about people:

How are social networks structured?

- ▶ How do we define and measure connections?
- ▶ Methods/issues of self-report and remote sensing.

What about the dynamics of social networks?

- ▶ How do social networks/movements begin & evolve?
- ▶ How does collective problem solving work?
- ▶ How does information move through social networks?
- ▶ Which rules give the best 'game of society'?

Sociotechnical phenomena and algorithms:

- ▶ What can people and computers do together? (google)
- ▶ Use **Play + Crunch** to solve problems. Which problems?

A small slice of the pie:

- ▶ **Q.** Can people pass messages between distant individuals using only their existing social connections?
- ▶ **A.** Apparently yes...

Milgram's social search experiment (1960s)

<http://www.stanleymilgram.com>

- ▶ Target person = Boston stockbroker.
- ▶ 296 senders from Boston and Omaha.
- ▶ 20% of senders reached target.
- ▶ chain length $\simeq 6.5$.

Popular terms:

- ▶ The Small World Phenomenon;
- ▶ “Six Degrees of Separation.”

The **SMALL WORLD** project is an online experiment to test the idea that any two people in the world can be connected via "six degrees of separation".

Your objective is to get a message to a "target person", somewhere in the world, by forwarding the message to a friend of yours—someone who is "closer" to the target than you are. (If you happen know the target, you can of course send it to them)

If we have asked you to participate (you would have received a message from a friend of yours), you should continue the chain.

If you are just visiting us, sign up to start a new chain.

Usefulness:

Harnessing social search:

- ▶ Can distributed social search be used for something big/good?
- ▶ What about something evil? (Good idea to check.)
- ▶ What about socio-inspired algorithms for information search? (More later.)
- ▶ For real social search, we have an incentives problem.
- ▶ Which kind of influence mechanisms/algorithms would help propagate search?
- ▶ Fun, money, prestige, ... ?
- ▶ Must be 'non-gameable.'

Red balloons:

A Grand Challenge:

- ▶ 1969: The Internet is born (田)
(the ARPANET (田)—four nodes!).
- ▶ Originally funded by DARPA who created a grand Network Challenge (田) for the 40th anniversary.
- ▶ Saturday December 5, 2009: DARPA puts 10 red weather balloons up during the day.
- ▶ Each 8 foot diameter balloon is anchored to the ground somewhere in the United States.
- ▶ Challenge: Find the latitude and longitude of each balloon.
- ▶ Prize: \$40,000.

* DARPA = Defense Advanced Research Projects Agency (田).

Where the balloons were:

Finding red balloons:

The winning team and strategy:

- ▶ MIT's Media Lab (田) won in less that 9 hours.
- ▶ People were virally recruited online to help out.
- ▶ Idea: Want people to both (1) find the balloons and (2) involve more people.
- ▶ Recursive incentive structure with exponentially decaying payout:
 - ▶ \$2000 for correctly reporting the coordinates of a balloon.
 - ▶ \$1000 for recruiting a person who finds a balloon.
 - ▶ \$500 for recruiting a person who recruits the balloon finder.
 - ▶ etc.

Finding balloons:

Clever scheme:

- ▶ Max payout = \$4000 per balloon.
- ▶ Individuals have clear incentives to both
 1. **involve/source more people** (spread), and
 2. **find balloons** (goal action).
- ▶ Gameable?
- ▶ Limit to how much money a set of bad actors can extract.

Extra notes:

- ▶ MIT's brand helped greatly.
- ▶ MIT group first heard about the competition a few days before. **Ouch.**
- ▶ A number of other teams did well (☒).
- ▶ Worthwhile looking at these competing strategies.

The social world appears to be small... why?

Theory: how do we understand the small world property?

- ▶ Connected **random networks** have short average path lengths:

$$\langle d_{AB} \rangle \sim \log(N)$$

N = population size,

d_{AB} = distance between nodes A and B .

- ▶ **But: social networks aren't random...**

Small-world networks

Introduced by Watts and Strogatz (Nature, 1998) [30]

“Collective dynamics of ‘small-world’ networks.”

Small-world networks were found everywhere:

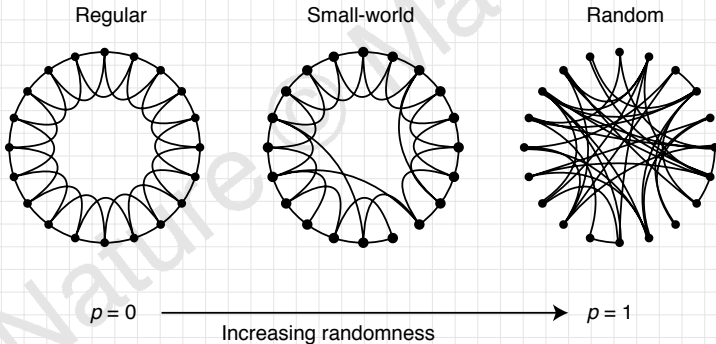

- ▶ neural network of *C. elegans*,
- ▶ semantic networks of languages,
- ▶ actor collaboration graph,
- ▶ food webs,
- ▶ social networks of comic book characters,...

Very weak requirements:

- ▶ local regularity + random short cuts

Toy model:

Previous work—finding short paths

Kleinberg's Network:

1. Start with regular d -dimensional cubic lattice.
2. Add local links so nodes know all nodes within a distance q .
3. Add m short cuts per node.
4. Connect i to j with probability

$$p_{ij} \propto x_{ij}^{-\alpha}.$$

- ▶ $\alpha = 0$: random connections.
- ▶ α large: reinforce local connections.
- ▶ $\alpha = d$: connections grow logarithmically in space.

Previous work—finding short paths

Theoretical optimal search:

- ▶ “Greedy” algorithm.
- ▶ Number of connections grow logarithmically (slowly) in space: $\alpha = d$.
- ▶ Social golf.

Search time grows slowly with system size (like $\log^2 N$).

But: social networks aren't lattices plus links.
