# net•work |'net,wɜrk|

noun

- 1 an arrangement of intersecting horizontal and vertical lines.
  - a complex system of roads, railroads, or other transportation routes : *a network of railroads.*
- 2 a group or system of interconnected people or things : *a trade network.*
  - a group of people who exchange information, contacts, and experience for professional or social purposes : *a support network.*
  - a group of broadcasting stations that connect for the simultaneous broadcast of a program : *the introduction of a second TV network* | [as adj. ] *network television.*
  - a number of interconnected computers, machines, or operations : *specialized computers that manage multiple outside connections to a network* | *a local cellular phone network.*
  - a system of connected electrical conductors.

verb [ trans. ]

connect as or operate with a network : *the stock exchanges have proven to be resourceful in networking these deals.*

- link (machines, esp. computers) to operate interactively : [as adj. ] ( **networked** ) *networked workstations.*
- [ intrans. ] [often as n. ] ( **networking** ) interact with other people to exchange information and develop contacts, esp. to further one's career : *the skills of networking, bargaining, and negotiation.*

## network

noun

- 1** *a network of arteries* WEB, lattice, net, matrix, mesh, crisscross, grid, reticulum, reticulation; Anatomy plexus.
- 2** *a network of lanes* MAZE, labyrinth, warren, tangle.
- 3** *a network of friends* SYSTEM, complex, nexus, web, webwork.

References

- ▶ **'Network'** = something built based on the idea of natural, flexible lattice or web.
- ▶ c.f., ironwork, stonework, fretwork.

# Key Observation:

- ▶ Many **complex systems** can be viewed as **complex networks** of physical or abstract interactions.
- ▶ Opens door to mathematical and numerical analysis.
- ▶ Dominant approach of last decade of a **theoretical-physics/stat-mechish** flavor.
- ▶ Mindboggling amount of work published on complex networks since 1998...
- ▶ ... largely due to your typical theoretical physicist:

- ▶ *Piranha physics*
- ▶ Hunt in packs.
- ▶ Feast on new and interesting ideas (see chaos, cellular automata, ...)

## Adjacency matrix:

- ▶ We represent a directed network by a matrix  $A$  with link weight  $a_{ij}$  for nodes  $i$  and  $j$  in entry  $(i, j)$ .
- ▶ e.g.,

$$A = \begin{bmatrix} 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 \end{bmatrix}$$

- ▶ (n.b., for numerical work, we always use sparse matrices.)

## So what passes for a complex network?

- ▶ Complex networks are **large** (in node number)
- ▶ Complex networks are **sparse** (low edge to node ratio)
- ▶ Complex networks are usually **dynamic** and **evolving**
- ▶ Complex networks can be social, economic, natural, informational, abstract, ...

## Physical networks

- ▶ River networks
- ▶ Neural networks
- ▶ Trees and leaves
- ▶ Blood networks
- ▶ The Internet
- ▶ Road networks
- ▶ Power grids

- ▶ **Distribution** (branching) versus **redistribution** (cyclical)

## A notable feature of large-scale networks:

- ▶ Graphical renderings are often just a big mess.

⇐ Typical hairball

- ▶ number of nodes  $N = 500$
  - ▶ number of edges  $m = 1000$
  - ▶ average degree  $\langle k \rangle = 4$
- ▶ And even when renderings somehow look good:  
 “That is a very graphic analogy which aids understanding wonderfully while being, strictly speaking, wrong in every possible way”  
 said Ponder [Stibbons] —*Making Money*, T. Pratchett.
- ▶ We need to extract **digestible, meaningful aspects**.

## Some key features of real complex networks:

- ▶ Degree distribution
- ▶ Assortativity
- ▶ Homophily
- ▶ Clustering
- ▶ Motifs
- ▶ Modularity
- ▶ Concurrency
- ▶ Hierarchical scaling
- ▶ Network distances
- ▶ Centrality
- ▶ Efficiency
- ▶ Robustness

- ▶ Coevolution of network **structure** and **processes** on networks.

## 1. Degree distribution $P_k$

- ▶  $P_k$  is the probability that a randomly selected node has degree  $k$
- ▶ **Big deal:** Form of  $P_k$  key to network's behavior
- ▶ **ex 1:** Erdős-Rényi random networks have a Poisson distribution:

$$P_k = e^{-\langle k \rangle} \langle k \rangle^k / k!$$

- ▶ **ex 2:** “Scale-free” networks:  $P_k \propto k^{-\gamma} \Rightarrow$  ‘hubs’
- ▶ We'll come back to this business soon...

## 2. Assortativity/3. Homophily:

- ▶ Social networks: Homophily (☐) = birds of a feather
- ▶ e.g., degree is standard property for sorting: measure degree-degree correlations.
- ▶ **Assortative** network: <sup>[20]</sup> similar degree nodes connecting to each other.
  - ▶ Often *social*: company directors, coauthors, actors.
- ▶ **Disassortative** network: high degree nodes connecting to low degree nodes.
  - ▶ Often *technological* or *biological*: Internet, protein interactions, neural networks, food webs.

## 4. Clustering:

- ▶ Your friends tend to know each other.
- ▶ Two measures:

$$C_1 = \left\langle \frac{\sum_{j_1, j_2 \in \mathcal{N}_i} a_{j_1 j_2}}{k_i(k_i - 1)/2} \right\rangle_i \text{ due to Watts \& Strogatz }^{[31]}$$

$$C_2 = \frac{3 \times \# \text{triangles}}{\# \text{triples}} \text{ due to Newman }^{[21]}$$

- ▶  $C_1$  is the **average fraction** of **pairs of neighbors** who are **connected**.
- ▶ Interpret  $C_2$  as probability two of a node's friends know each other.

## 5. Motifs:

- ▶ Small, recurring functional subnetworks
- ▶ e.g., Feed Forward Loop:

Shen-Orr, Uri Alon, *et al.* [24]

## 6. modularity:

Clauset *et al.*, 2006<sup>[10]</sup>: NCAA football

## 7. Concurrency:

- ▶ Transmission of a contagious element only occurs during contact<sup>[18]</sup>
- ▶ Rather obvious but easily missed in a simple model
- ▶ Dynamic property—static networks are not enough
- ▶ Knowledge of previous contacts crucial
- ▶ **Beware** cumulated network data!

## 8. Horton-Strahler stream ordering:

- ▶ Metrics for branching networks:
  - ▶ Method for ordering streams hierarchically
  - ▶ Reveals fractal nature of natural branching networks
  - ▶ Hierarchy is not pure but mixed (Tokunaga). [26, 12]
  - ▶ Major examples: rivers and blood networks.

- ▶ Beautifully described but poorly explained.

## 9. Network distances:

### (a) shortest path length $d_{ij}$ :

- ▶ Fewest number of steps between nodes  $i$  and  $j$ .
- ▶ (Also called the chemical distance between  $i$  and  $j$ .)

### (b) average path length $\langle d_{ij} \rangle$ :

- ▶ Average shortest path length in whole network.
- ▶ Good algorithms exist for calculation.
- ▶ Weighted links can be accommodated.

## 9. Network distances:

### (c) Network diameter $d_{\max}$ :

- ▶ Maximum shortest path length in network.

### (d) Closeness $d_{cl} = [\sum_{ij} d_{ij}^{-1} / \binom{n}{2}]^{-1}$ :

- ▶ Average 'distance' between any two nodes.
- ▶ Closeness handles disconnected networks ( $d_{ij} = \infty$ )
- ▶  $d_{cl} = \infty$  only when all nodes are isolated.

## 10. Centrality:

- ▶ Many such measures of a node's 'importance.'
- ▶ **ex 1:** Degree centrality:  $k_i$ .
- ▶ **ex 2:** Node  $i$ 's betweenness  
= fraction of shortest paths that pass through  $i$ .
- ▶ **ex 3:** Edge  $\ell$ 's betweenness  
= fraction of shortest paths that travel along  $\ell$ .
- ▶ **ex 4:** Recursive centrality: Hubs and Authorities (Jon Kleinberg<sup>[17]</sup>)

## Overview Key Points:

- ▶ The field of complex networks came into existence in the late 1990s.
- ▶ Explosion of papers and interest since 1998/99.
- ▶ Hardened up much thinking about complex systems.
- ▶ Specific focus on networks that are **large-scale**, **sparse**, **natural** or **man-made**, **evolving** and **dynamic**, and (crucially) **measurable**.
- ▶ Three main (blurred) categories:
  1. **Physical** (e.g., river networks),
  2. **Interactional** (e.g., social networks),
  3. **Abstract** (e.g., thesauri).

## Overview Key Points (cont.):

- ▶ Obvious connections with the vast extant field of graph theory.
- ▶ But focus on dynamics is more of a physics/stat-mech/comp-sci flavor.
- ▶ Two main areas of focus:
  1. **Description:** Characterizing very large networks
  2. **Explanation:** Micro story  $\Rightarrow$  Macro features
- ▶ Some essential structural aspects are understood: degree distribution, clustering, assortativity, group structure, overall structure,...
- ▶ Still much work to be done, especially with respect to dynamics...

## Generalized random networks:

- ▶ Arbitrary degree distribution  $P_k$ .
- ▶ Create (unconnected) nodes with degrees sampled from  $P_k$ .
- ▶ Wire nodes together randomly.
- ▶ Create ensemble to test deviations from randomness.

# Building random networks: Stubs

## Phase 1:

- ▶ **Idea:** start with a soup of unconnected nodes with **stubs** (half-edges):

- ▶ Randomly select stubs (not nodes!) and connect them.
- ▶ Must have an even number of stubs.
- ▶ Initially allow **self-** and **repeat** connections.

Basic definitions

Basic models of  
complex networks

Generalized random  
networks

Scale-free networks

Small-world networks

Generalized affiliation  
networks

References

# Building random networks: First rewiring

## Phase 2:

- ▶ Now find any (A) self-loops and (B) repeat edges and **randomly rewire** them.

- ▶ **Being careful:** we can't change the degree of any node, so we can't simply move links around.
- ▶ **Simplest solution:** randomly rewire **two edges** at a time.

# General random rewiring algorithm

- ▶ Randomly choose **two edges**. (Or choose problem edge and a random edge)
- ▶ Check to make sure edges are **disjoint**.
- ▶ Rewire one end of each edge.
- ▶ Node degrees **do not change**.
- ▶ Works if  $e_1$  is a self-loop or repeated edge.
- ▶ Same as finding on/off/on/off 4-cycles. and rotating them.

References

# Sampling random networks

## Phase 2:

- ▶ Use rewiring algorithm to remove all self and repeat loops.

## Phase 3:

- ▶ **Randomize network** wiring by applying rewiring algorithm liberally.
- ▶ **Rule of thumb:** # Rewirings  $\simeq 10 \times$  # edges<sup>[19]</sup>.

# Scale-free networks

- ▶ Networks with power-law degree distributions have become known as **scale-free** networks.
- ▶ Scale-free refers specifically to the **degree distribution** having a **power-law decay** in its tail:

$$P_k \sim k^{-\gamma} \text{ for 'large' } k$$

- ▶ One of the seminal works in complex networks: Laszlo Barabási and Reka Albert, Science, 1999: “Emergence of scaling in random networks” [4]
- ▶ Somewhat misleading nomenclature...

## The big deal:

- ▶ We move beyond describing networks to finding **mechanisms** for why certain networks are the way they are.

## A big deal for scale-free networks:

- ▶ How does the exponent  $\gamma$  depend on the mechanism?
- ▶ Do the mechanism details matter?

- ▶ Barabási-Albert model = BA model.
- ▶ Key ingredients:  
**Growth** and **Preferential Attachment (PA)**.
- ▶ **Step 1**: start with  $m_0$  disconnected nodes.
- ▶ **Step 2**:
  1. **Growth**—a new node appears at each time step  $t = 0, 1, 2, \dots$
  2. Each new node makes  $m$  links to nodes already present.
  3. **Preferential attachment**—Probability of connecting to  $i$ th node is  $\propto k_i$ .
- ▶ In essence, we have a **rich-gets-richer** scheme.

- ▶ **Definition:**  $A_k$  is the **attachment kernel** for a node with degree  $k$ .
- ▶ For the original model:

$$A_k = k$$

- ▶ **Definition:**  $P_{\text{attach}}(k, t)$  is the attachment probability.
- ▶ For the original model:

$$P_{\text{attach}}(\text{node } i, t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{\max}(t)} k N_k(t)}$$

where  $N(t) = m_0 + t$  is # nodes at time  $t$   
and  $N_k(t)$  is # degree  $k$  nodes at time  $t$ .

# Approximate analysis

- ▶ When  $(N + 1)$ th node is added, the expected increase in the degree of node  $i$  is

$$E(k_{i,N+1} - k_{i,N}) \simeq m \frac{k_{i,N}}{\sum_{j=1}^{N(t)} k_j(t)}.$$

- ▶ Assumes probability of being connected to is **small**.
- ▶ Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.
- ▶ Approximate  $k_{i,N+1} - k_{i,N}$  with  $\frac{d}{dt}k_{i,t}$ :

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where  $t = N(t) - m_0$ .

# Approximate analysis

- ▶ Deal with denominator: each added node brings  $m$  new edges.

$$\therefore \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

- ▶ The node degree equation now simplifies:

$$\frac{d}{dt} k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = m \frac{k_i(t)}{2mt} = \frac{1}{2t} k_i(t)$$

- ▶ Rearrange and solve:

$$\frac{dk_i(t)}{k_i(t)} = \frac{dt}{2t} \Rightarrow k_i(t) = c_i t^{1/2}.$$

- ▶ Next find  $c_i$  ...

# Approximate analysis

- ▶ Know  $i$ th node appears at time

$$t_{i,\text{start}} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

- ▶ So for  $i > m_0$  (exclude initial nodes), we must have

$$k_i(t) = m \left( \frac{t}{t_{i,\text{start}}} \right)^{1/2} \quad \text{for } t \geq t_{i,\text{start}}.$$

- ▶ All node degrees grow as  $t^{1/2}$  but later nodes have larger  $t_{i,\text{start}}$  which **flattens out** growth curve.
- ▶ Early nodes do **best** (First-mover advantage).

# Approximate analysis

▶  $m = 3$

▶  $t_{i,start} =$   
1, 2, 5, and 10.

# Degree distribution

- ▶ So what's the **degree distribution** at time  $t$ ?
- ▶ Use fact that birth time for added nodes is distributed uniformly:

$$\Pr(t_{i,\text{start}})dt_{i,\text{start}} \simeq \frac{dt_{i,\text{start}}}{t}$$

- ▶ Also use

$$k_i(t) = m \left( \frac{t}{t_{i,\text{start}}} \right)^{1/2} \Rightarrow t_{i,\text{start}} = \frac{m^2 t}{k_i(t)^2}.$$

Transform variables—Jacobian:

$$\frac{dt_{i,\text{start}}}{dk_i} = -2 \frac{m^2 t}{k_i(t)^3}.$$

WWW	$\gamma \simeq 2.1$ for in-degree
WWW	$\gamma \simeq 2.45$ for out-degree
Movie actors	$\gamma \simeq 2.3$
Words (synonyms)	$\gamma \simeq 2.8$

The Internet **s** is a different business...

From Barabási and Albert's original paper [4]:

**Fig. 1.** The distribution function of connectivities for various large networks. **(A)** Actor collaboration graph with  $N = 212,250$  vertices and average connectivity  $\langle k \rangle = 28.78$ . **(B)** WWW,  $N = 325,729$ ,  $\langle k \rangle = 5.46$ . **(C)** Power grid data,  $N = 4941$ ,  $\langle k \rangle = 2.67$ . The dashed lines have slopes **(A)**  $\gamma_{\text{actor}} = 2.3$ , **(B)**  $\gamma_{\text{www}} = 2.1$  and **(C)**  $\gamma_{\text{power}} = 4$ .

# Things to do and questions

- ▶ Vary attachment kernel.
- ▶ Vary mechanisms:
  1. Add edge deletion
  2. Add node deletion
  3. Add edge rewiring
- ▶ Deal with directed versus undirected networks.
- ▶ **Important Q.:** Are there distinct universality classes for these networks?
- ▶ **Q.:** How does changing the model affect  $\gamma$ ?
- ▶ **Q.:** Do we need preferential attachment and growth?
- ▶ **Q.:** Do model details matter?
- ▶ The answer is (surprisingly) **yes**. See Simon's model of Zipf.

# Preferential attachment

- ▶ Let's look at preferential attachment (PA) a little more closely.
- ▶ PA implies arriving nodes have **complete knowledge** of the existing network's degree distribution.
- ▶ For example: If  $P_{\text{attach}}(k) \propto k$ , we need to determine the constant of proportionality.
- ▶ We need to know what everyone's degree is...
- ▶ PA is  $\therefore$  an **outrageous** assumption of node capability.
- ▶ But a **very simple mechanism** saves the day...

# Preferential attachment through randomness

- ▶ Instead of attaching preferentially, allow new nodes to attach randomly.
- ▶ Now add an **extra step**: new nodes then connect to some of their friends' friends.
- ▶ Can also do this **at random**.
- ▶ Assuming the existing network is random, we know probability of a **random friend** having degree  $k$  is

$$Q_k \propto kP_k$$

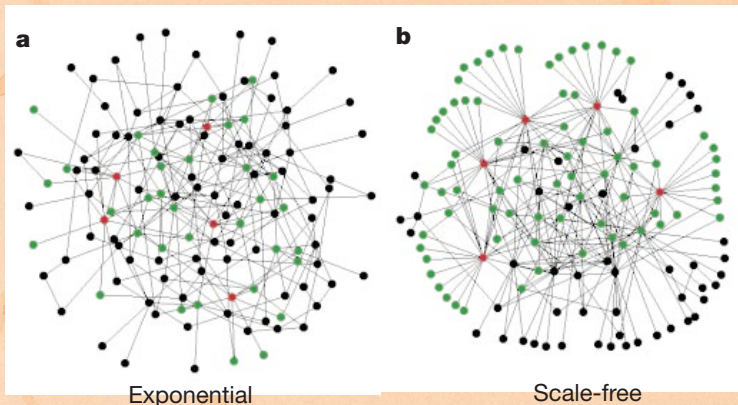

- ▶ So **rich-gets-richer** scheme can now be seen to work in a natural way.

# Previous work—finding short paths

## Kleinberg's Network:

1. Start with regular  $d$ -dimensional cubic lattice.
2. Add local links so nodes know all nodes within a distance  $q$ .
3. Add  $m$  short cuts per node.
4. Connect  $i$  to  $j$  with probability

$$p_{ij} \propto x_{ij}^{-\alpha}.$$

- ▶  $\alpha = 0$ : random connections.
- ▶  $\alpha$  large: reinforce local connections.
- ▶  $\alpha = d$ : connections grow logarithmically in space.

# Previous work—finding short paths

## Theoretical optimal search:

- ▶ “Greedy” algorithm.
- ▶ Number of connections grow logarithmically (slowly) in space:  $\alpha = d$ .
- ▶ Social golf.

Search time grows slowly with system size (like  $\log^2 N$ ).

**But: social networks aren't lattices plus links.**

If there are no hubs and no underlying lattice, how can search be efficient?

Which friend of **a** is closest to the target **b**?

What does 'closest' mean?

What is 'social distance'?

One approach: incorporate **identity**.

**Identity is formed from attributes such as:**

- ▶ Geographic location
- ▶ Type of employment
- ▶ Religious beliefs
- ▶ Recreational activities.

**Groups** are formed by people with at least one similar attribute.

Attributes  $\Leftrightarrow$  Contexts  $\Leftrightarrow$  Interactions  $\Leftrightarrow$  Networks.

## Nutshell for Small-World Networks:

- ▶ Bare networks are typically unsearchable.
- ▶ Paths are findable if nodes understand how network is formed.
- ▶ Importance of identity (interaction contexts).
- ▶ Improved social network models.
- ▶ Construction of peer-to-peer networks.
- ▶ Construction of searchable information databases.
