Robustness

- ▶ System robustness may result from
 1. Evolutionary processes
 2. Engineering/Design
- ▶ Idea: Explore systems optimized to perform under uncertain conditions.
- ▶ The handle: 'Highly Optimized Tolerance' (HOT) [4, 5, 6, 9]
- ▶ The catchphrase: Robust yet Fragile
- ▶ The people: Jean Carlson and John Doyle (JD)

Robustness

Features of HOT systems: [5, 6]

- ▶ High performance and robustness
- ▶ Designed/evolved to handle known stochastic environmental variability
- ▶ Fragile in the face of unpredicted environmental signals
- ▶ Highly specialized, low entropy configurations
- ▶ Power-law distributions appear (of course...)

Robustness

- ▶ Many complex systems are prone to cascading catastrophic failure: exciting!!!
 - ▶ Blackouts
 - ▶ Disease outbreaks
 - ▶ Wildfires
 - ▶ Earthquakes
- ▶ But complex systems also show persistent robustness (not as exciting but important...)
- ▶ Robustness and Failure may be a power-law story...

Robustness

HOT combines things we've seen:

- ▶ Variable transformation
- ▶ Constrained optimization
- ▶ Need power law transformation between variables: $(Y = X^{-\alpha})$
- ▶ Recall PLIPLO is bad...
- ▶ MIWO is good: Mild In, Wild Out
- ▶ X has a characteristic size but Y does not

Robustness

Forest fire example: [5]

- ▶ Square $N \times N$ grid
- ▶ Sites contain a tree with probability $\rho = \text{density}$
- ▶ Sites are empty with probability $1 - \rho$
- ▶ Fires start at location (i, j) according to some distribution P_{ij}
- ▶ Fires spread from tree to tree (nearest neighbor only)
- ▶ Connected clusters of trees burn completely
- ▶ Empty sites block fire
- ▶ **Best case scenario:**
Build firebreaks to maximize average # trees left intact given one spark

System Robustness

Robustness
HOT theory
Self-Organized Criticality
COLD theory
Network robustness
References

HOT Forests

$N = 64$

- (a) $D = 1$
- (b) $D = 2$
- (c) $D = N$
- (d) $D = N^2$

P_{ij} has a Gaussian decay

- ▶ Optimized forests do well on average (**robustness**)
- ▶ But rare extreme events occur (**fragility**)

System Robustness

Robustness
HOT theory
Self-Organized Criticality
COLD theory
Network robustness
References

Robustness

Forest fire example: [5]

- ▶ Build a forest by adding one tree at a time
- ▶ Test D ways of adding one tree
- ▶ $D = \text{design parameter}$
- ▶ Average over $P_{ij} = \text{spark probability}$
- ▶ $D = 1$: random addition
- ▶ $D = N^2$: test all possibilities

Measure average area of forest left untouched

- ▶ $f(c) = \text{distribution of fire sizes } c (= \text{cost})$
- ▶ Yield = $Y = \rho - \langle c \rangle$

HOT Forests

FIG. 2. Yield vs density $Y(\rho)$: (a) for design parameters $D = 1$ (dotted curve), 2 (dot-dashed), N (long dashed), and N^2 (solid) with $N = 64$, and (b) for $D = 2$ and $N = 2, 2^2, \dots, 2^7$ running from the bottom to top curve. The results have been averaged over 100 runs. The inset to (a) illustrates corresponding loss functions $L = \log[\langle f \rangle / (1 - \langle f \rangle)]$, on a scale which more clearly differentiates between the curves.

Robustness

Specifics:

- ▶ $P_{ij} = P_{i,a_x, b_x} P_{j,a_y, b_y}$
- ▶ where $P_{i,a,b} \propto e^{-[(i+a)/b]^2}$
- ▶ In the original work, $b_y > b_x$
- ▶ Distribution has more width in y direction.

System Robustness

Robustness
HOT theory
Self-Organized Criticality
COLD theory
Network robustness
References

HOT Forests:

- ▶ $Y = \text{'the average density of trees left unburned in a configuration after a single spark hits.'}$ [5]

FIG. 3. Cumulative distributions of events $F(c)$: (a) at peak yield for $D = 1, 2, N$, and N^2 with $N = 64$, and (b) for $D = N^2$, and $N = 64$ at equal density increments of 0.1 , ranging at $\rho = 0.1$ (bottom curve) to $\rho = 0.9$ (top curve).

Random Forests

$D = 1$: Random forests = Percolation^[10]

- ▶ Randomly add trees
- ▶ Below critical density ρ_c , no fires take off
- ▶ Above critical density ρ_c , percolating cluster of trees burns
- ▶ Only at ρ_c , the critical density, is there a power-law distribution of tree cluster sizes
- ▶ Forest is random and featureless

HOT forests

HOT forests nutshell:

- ▶ Highly structured
- ▶ Power law distribution of tree cluster sizes for $\rho > \rho_c$
- ▶ No specialness of ρ_c
- ▶ Forest states are **tolerant**
- ▶ Uncertainty is okay if well characterized
- ▶ If P_{ij} is characterized poorly, failure becomes **highly likely**

HOT forests—Real data:^[6]

Fig. 1. Log-log (base 10) comparison of DC, WWW, CF, and FF data (symbols) with PLR models (solid lines) (for $\beta = 0, 0.9, 0.9, 1.85$, or $\alpha = 1/\beta = \infty, 1.1, 1.1, 0.054$, respectively) and the SOC FF model ($\alpha = 0.15$, dashed). Reference lines of $\alpha = 0.5, 1$ (dashed) are included. The cumulative distributions of frequencies $\mathcal{P}(l = l)$ vs. l describe the areas burned in the largest 4,284 fires from 1986 to 1995 on all of the U.S. Fish and Wildlife Service Lands (FF) (17), the >10,000 largest California brushfires from 1878 to 1999 (CF) (18), 130,000 web file transfers at Boston University during 1994 and 1995 (WWW) (19), and code words from DC. The size units [1,000 km² (FF and CF), megabytes (WWW), and bytes (DC)] and the logarithmic decimation of the data are chosen for visualization.

- ▶ PLR = probability-loss-resource.
- ▶ Minimize cost subject to resource (barrier) constraints: $\{J = \sum_i p_i l_i | l_i = f(r_i), \sum r_i \leq R\}$

HOT theory

The abstract story:

- ▶ Given $y_i = x_i^{-\alpha}$, $i = 1, \dots, N_{\text{sites}}$
- ▶ Design system to minimize $\langle y \rangle$ subject to a constraint on the x_i
- ▶ Minimize cost:

$$C = \sum_{i=1}^{N_{\text{sites}}} Pr(y_i) y_i$$

Subject to $\sum_{i=1}^{N_{\text{sites}}} x_i = \text{constant}$

- ▶ Drag out the Lagrange Multipliers, battle away and find:

$$p_i \propto y_i^{-\gamma}$$

HOT Theory—Two costs:

1. Expected size of fire:

$$C_{\text{fire}} \propto \sum_{i=1}^{N_{\text{sites}}} (p_i a_i) a_i = \sum_{i=1}^{N_{\text{sites}}} p_i a_i^2$$

- ▶ a_i = area of i th site's region
- ▶ p_i = avg. prob. of fire at site in i th site's region
- ▶ N_{sites} = total number of sites

2. Cost of building and maintaining firewalls

$$C_{\text{firewalls}} \propto \sum_{i=1}^{N_{\text{sites}}} a_i^{1/2} a_i^{-1}$$

- ▶ We are assuming **isometry**.
- ▶ In d dimensions, $1/2$ is replaced by $(d-1)/d$

HOT theory

Extra constraint:

- ▶ Total area is constrained:

$$\sum_{i=1}^{N_{\text{sites}}} 1 = N^2.$$

$$\sum_{i=1}^{N_{\text{sites}}} \frac{1}{a_i} = N_{\text{regions}}$$

where N_{regions} = number of cells.

- ▶ Can ignore in calculation...

HOT theory

- ▶ Minimize C_{fire} given $C_{\text{firewalls}} = \text{constant}$.

$$0 = \frac{\partial}{\partial a_j} (C_{\text{fire}} - \lambda C_{\text{firewalls}})$$

$$\propto \frac{\partial}{\partial a_j} \left(\sum_{i=1}^N p_i a_i^2 - \lambda' a_i^{(d-1)/d} a_i^{-1} \right)$$

$$p_i \propto a_i^{-\gamma} = a_i^{-(2+1/d)}$$

$$\text{For } d = 2, \gamma = 5/2$$

SOC theory

SOC = Self-Organized Criticality

- ▶ Idea: natural dissipative systems exist at 'critical states'
- ▶ Analogy: Ising model with temperature somehow self-tuning
- ▶ Power-law distributions of sizes and frequencies arise 'for free'
- ▶ Introduced in 1987 by Bak, Tang, and Wiesenfeld [3, 2, 7]: "Self-organized criticality - an explanation of 1/f noise" (PRL, 1987).
- ▶ **Problem:** Critical state is a very specific point
- ▶ Self-tuning not always possible
- ▶ Much criticism and arguing...

HOT theory

Summary of designed tolerance [6]

- ▶ Build more firewalls in areas where sparks are likely
- ▶ Small connected regions in high-danger areas
- ▶ Large connected regions in low-danger areas
- ▶ Routinely see many small outbreaks (**robust**)
- ▶ Rarely see large outbreaks (**fragile**)
- ▶ Sensitive to changes in the environment (P_{ij})

Robustness

HOT versus SOC

- ▶ Both produce power laws
- ▶ Optimization versus self-tuning
- ▶ HOT systems viable over a wide range of high densities
- ▶ SOC systems have one special density
- ▶ HOT systems produce specialized structures
- ▶ SOC systems produce generic structures

HOT theory—Summary of designed tolerance [6]

Table 1. Characteristics of SOC, HOT, and data

	Property	SOC	HOT and Data
1	Internal configuration	Generic, homogeneous, self-similar	Structured, heterogeneous, self-dissimilar
2	Robustness	Generic	Robust, yet fragile
3	Density and yield	Low	High
4	Max event size	Infinitesimal	Large
5	Large event shape	Fractal	Compact
6	Mechanism for power laws	Critical internal fluctuations	Robust performance
7	Exponent α	Small	Large
8	α vs. dimension d	$\alpha \approx (d - 1)/10$	$\alpha \approx 1/d$
9	DDOFs	Small (1)	Large (∞)
10	Increase model resolution	No change	New structures, new sensitivities
11	Response to forcing	Homogeneous	Variable

COLD forests

Avoidance of large-scale failures

- ▶ Constrained Optimization with Limited Deviations [8]
- ▶ Weight cost of large losses more strongly
- ▶ Increases average cluster size of burned trees...
- ▶ ... but reduces chances of catastrophe
- ▶ Power law distribution of fire sizes is truncated

Cutoffs

Aside:

- ▶ Power law distributions often have an exponential cutoff

$$P(x) \sim x^{-\gamma} e^{-x/x_c}$$

where x_c is the approximate cutoff scale.

- ▶ May be Weibull distributions:

$$P(x) \sim x^{-\gamma} e^{-ax^{-\gamma+1}}$$
