Two focuses for us

- ▶ Widespread media influence
- ▶ Word-of-mouth influence

We need to understand influence

- ▶ Who influences whom? Very hard to measure...
- ▶ What kinds of influence response functions are there?
- ▶ Are some individuals super influencers?
Highly popularized by Gladwell^[9] as 'connectors'
- ▶ The infectious idea of opinion leaders (Katz and Lazarsfeld)^[13]

The hypodermic model of influence

Why do things spread?

- ▶ Because of properties of special individuals?
- ▶ Or system level properties?
- ▶ Is the match that lights the fire important?
- ▶ Yes. But only because we are narrative-making machines...
- ▶ We like to think things happened for reasons...
- ▶ Reasons for success are usually ascribed to intrinsic properties (e.g., Mona Lisa)
- ▶ System/group properties harder to understand
- ▶ Always good to examine what is said before and after the fact...

Background

Granovetter's model

Network version

Groups

Chaos

References

- ▶ Cialdini's modes are heuristics that help up us get through life.
- ▶ Useful but can be leveraged...

Other acts of influence:

- ▶ Conspicuous Consumption (Veblen, 1912)
- ▶ Conspicuous Destruction (Potlatch)

Some important models

- ▶ Tipping models—Schelling (1971) [16, 17, 18]
 - ▶ Simulation on checker boards
 - ▶ Idea of thresholds
 - ▶ Explore the Netlogo (田) implementation [21]
- ▶ Threshold models—Granovetter (1978) [10]
- ▶ Herding models—Bikhchandani, Hirschleifer, Welch (1992) [1, 2]
 - ▶ Social learning theory, Informational cascades,...

Thresholds

- ▶ Basic idea: individuals adopt a behavior when a **certain fraction of others** have adopted
- ▶ 'Others' may be everyone in a population, an individual's close friends, any reference group.
- ▶ Response can be probabilistic or deterministic.
- ▶ Individual thresholds can vary
- ▶ Assumption: order of others' adoption does not matter... (**unrealistic**).
- ▶ Assumption: level of influence per person is uniform (**unrealistic**).

Social Contagion Models

Background

Granovetter's model

Network version

Groups

Chaos

References

Some possible origins of thresholds:

- ▶ **Desire to coordinate**, to conform.
- ▶ **Lack of information**: impute the worth of a good or behavior based on degree of adoption (social proof)
- ▶ Economics: **Network effects** or **network externalities**
- ▶ Externalities = Effects on others not directly involved in a transaction
- ▶ Examples: telephones, fax machine, Facebook, operating systems
- ▶ An individual's utility increases with the adoption level among peers and the population in general

Granovetter's Threshold model—definitions

- ▶ ϕ^* = threshold of an individual.
- ▶ $f(\phi_*)$ = distribution of thresholds in a population.
- ▶ $F(\phi_*)$ = cumulative distribution = $\int_{\phi'_*=0}^{\phi_*} f(\phi'_*)d\phi'_*$
- ▶ ϕ_t = fraction of people 'rioting' at time step t .

Threshold models

- ▶ Example threshold influence response functions: **deterministic** and **stochastic**
- ▶ ϕ = fraction of contacts 'on' (e.g., rioting)
- ▶ Two states: S and I.

Social Contagion Models

- Background
- Granovetter's model**
- Network version
- Groups
- Chaos

References

- ▶ At time $t + 1$, fraction rioting = fraction with $\phi_* \leq \phi_t$.

$$\phi_{t+1} = \int_0^{\phi_t} f(\phi_*) d\phi_* = F(\phi_*)|_0^{\phi_t} = F(\phi_t)$$

- ▶ \Rightarrow Iterative maps of the unit interval $[0, 1]$.

Action based on perceived behavior of others.

- ▶ Two states: S and I.
- ▶ ϕ = fraction of contacts 'on' (e.g., rioting)
- ▶ Discrete time update (strong assumption!)
- ▶ This is a **Critical mass model**

▶ Another example of critical mass model...

Threshold models

► Example of single stable state model

Social Contagion Models

Implications for collective action theory:

1. Collective uniformity \nrightarrow individual uniformity
2. Small individual changes \Rightarrow large global changes

Chaotic behavior possible [12, 11]

- ▶ Period doubling arises as map amplitude r is increased.
- ▶ Synchronous update assumption is crucial

Many years after Granovetter and Soong's work:

“A simple model of global cascades on random networks”

D. J. Watts. Proc. Natl. Acad. Sci., 2002 ^[20]

- ▶ Mean field model → network model
- ▶ Individuals now have a limited view of the world

Threshold model on a network

- ▶ Interactions between individuals now represented by a network
- ▶ Network is **sparse**
- ▶ Individual i has k_i contacts
- ▶ Influence on each link is **reciprocal** and of **unit weight**
- ▶ Each individual i has a fixed threshold ϕ_i
- ▶ Individuals repeatedly poll contacts on network
- ▶ Synchronous, discrete time updating
- ▶ Individual i becomes active when fraction of active contacts $\frac{a_i}{k_i} \geq \phi_i$
- ▶ Individuals remain active when switched (no recovery = SI model)

Threshold model on a network

► All nodes have threshold $\phi = 0.2$.

The Cascade Condition:

1. If one individual is initially activated, what is the probability that an activation will spread over a network?
2. What features of a network determine whether a cascade will occur or not?

First study random networks:

- ▶ Start with N nodes with a degree distribution p_k
- ▶ Nodes are randomly connected (carefully so)
- ▶ Aim: Figure out when activation will propagate
- ▶ Determine a **cascade condition**

Follow active links

- ▶ An active link is a link connected to an activated node.
- ▶ If an infected link leads to **at least 1 more infected link**, then **activation spreads**.
- ▶ We need to understand which nodes can be activated when only one of their neighbors becomes active.

Vulnerables:

- ▶ We call individuals who can be activated by just one contact being active **vulnerables**
- ▶ The vulnerability condition for node i :

$$1/k_i \geq \phi_i$$

- ▶ Which means # contacts $k_i \leq \lfloor 1/\phi_i \rfloor$
- ▶ For global cascades on random networks, must have a *global cluster of vulnerables* ^[20]
- ▶ **Cluster of vulnerables = critical mass**
- ▶ Network story: 1 node \rightarrow critical mass \rightarrow everyone.

Back to following a link:

- ▶ A randomly chosen link, traversed in a random direction, leads to a degree k node with probability $\propto kP_k$.

- ▶ Follows from there being k ways to connect to a node with degree k .

- ▶ Normalization:

$$\sum_{k=0}^{\infty} kP_k = \langle k \rangle$$

- ▶ So

$$P(\text{linked node has degree } k) = \frac{kP_k}{\langle k \rangle}$$

Next: Vulnerability of linked node

- ▶ Linked node is **vulnerable** with probability

$$\beta_k = \int_{\phi'_*=0}^{1/k} f(\phi'_*) d\phi'_*$$

- ▶ If linked node is **vulnerable**, it produces **$k - 1$ new** outgoing active links
- ▶ If linked node is **not vulnerable**, it produces **no** active links.

Putting things together:

- ▶ Expected number of active edges produced by an active edge:

$$R = \sum_{k=1}^{\infty} \underbrace{(k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle}}_{\text{success}} + \underbrace{0 \cdot (1 - \beta_k) \cdot \frac{kP_k}{\langle k \rangle}}_{\text{failure}}$$
$$= \sum_{k=1}^{\infty} (k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle}$$

So... for random networks with fixed degree distributions, cascades take off when:

$$\sum_{k=1}^{\infty} (k-1) \cdot \beta_k \cdot \frac{kP_k}{\langle k \rangle} \geq 1.$$

- ▶ β_k = probability a degree k node is vulnerable.
- ▶ P_k = probability a node has degree k .

Two special cases:

- ▶ (1) Simple disease-like spreading succeeds: $\beta_k = \beta$

$$\beta \cdot \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} \geq 1.$$

- ▶ (2) Giant component exists: $\beta = 1$

$$1 \cdot \sum_{k=1}^{\infty} (k-1) \cdot \frac{kP_k}{\langle k \rangle} \geq 1.$$

Cascades on random networks

- ▶ Cascades occur only if size of max vulnerable cluster > 0 .
- ▶ System may be 'robust-yet-fragile'.
- ▶ 'Ignorance' facilitates spreading.

Cascade window for random networks

- ▶ 'Cascade window' widens as threshold ϕ decreases.
- ▶ Lower thresholds enable spreading.

Cascade window for random networks

Social Contagion Models

Background
Granovetter's model

Network version

Groups
Chaos

References

For our simple model of a uniform threshold:

1. **Low** $\langle k \rangle$: No cascades in poorly connected networks. No global clusters of any kind.
2. **High** $\langle k \rangle$: Giant component exists but not enough vulnerables.
3. **Intermediate** $\langle k \rangle$: Global cluster of vulnerables exists. Cascades are possible in “**Cascade window.**”

Multiplier effect for group-based networks:

► Multiplier almost always below 1.

Assortativity in group-based networks

- ▶ The most connected nodes aren't always the most 'influential.'
- ▶ **Degree assortativity** is the reason.

Summary

- ▶ 'Influential vulnerables' are key to spread.
- ▶ Early adopters are mostly vulnerables.
- ▶ Vulnerable nodes important but not necessary.
- ▶ Groups may greatly facilitate spread.
- ▶ Seems that cascade condition is a global one.
- ▶ Most extreme/unexpected cascades occur in highly connected networks
- ▶ 'Influentials' are posterior constructs.
- ▶ Many potential influentials exist.

Social Contagion Models

Background
Granovetter's model
Network version
Groups
Chaos

References

Implications

- ▶ Focus on **the influential vulnerables**.
- ▶ Create entities that can be transmitted successfully through many individuals rather than broadcast from one 'influential.'
- ▶ Only **simple ideas** can spread by word-of-mouth.
(Idea of opinion leaders spreads well...)
- ▶ Want enough individuals who will adopt and display.
- ▶ Displaying can be **passive** = free (yo-yo's, fashion), or **active** = harder to achieve (political messages).
- ▶ Entities can be novel or designed to combine with others, e.g. block another one.

Social Contagion Models

Background
Granovetter's model
Network version
Groups
Chaos

References

- ▶ What if individual response functions are not monotonic?
- ▶ Consider a simple deterministic version:
 - ▶ Node i has an 'activation threshold' $\phi_{i,1}$
... and a 'de-activation threshold' $\phi_{i,2}$
 - ▶ Nodes like to imitate but only up to a limit—they don't want to be like everyone else.

Two population examples:

- ▶ Randomly select $(\phi_{i,1}, \phi_{i,2})$ from gray regions shown in plots B and C.
- ▶ Insets show composite response function averaged over population.
- ▶ We'll consider plot C's example: [the tent map](#).

Social Contagion Models

Coupled maps are well explored
(Kaneko/Kuramoto):

$$x_{i,n+1} = f(x_{i,n}) + \sum_{j \in \mathcal{N}_i} \delta_{i,j} f(x_{j,n})$$

► \mathcal{N}_i = neighborhood of node i

1. Node states are **continuous**
2. Increase δ and neighborhood size $|\mathcal{N}|$
 \Rightarrow **synchronization**

But for contagion model:

1. Node states are **binary**
2. **Asynchrony remains** as connectivity increases

Bifurcation diagram: Asynchronous updating
