## Models

### Some important models:

1. Generalized random networks;
2. Small-world networks;
3. Generalized affiliation networks;
4. Scale-free networks;
5. Statistical generative models ( $p^*$ ).

## Models

### Generalized random networks:

- ▶ Arbitrary degree distribution  $P_k$ .
- ▶ Create (unconnected) nodes with degrees sampled from  $P_k$ .
- ▶ Wire nodes together randomly.
- ▶ Create ensemble to test deviations from randomness.

## Building random networks: Stubs

### Phase 1:

- ▶ **Idea:** start with a soup of unconnected nodes with stubs (half-edges):

- ▶ Randomly select stubs (not nodes!) and connect them.
- ▶ Must have an even number of stubs.
- ▶ Initially allow **self-** and **repeat** connections.

## Building random networks: First rewiring

### Phase 2:

- ▶ Now find any (A) self-loops and (B) repeat edges and **randomly rewire** them.

- ▶ **Being careful:** we can't change the degree of any node, so we can't simply move links around.
- ▶ **Simplest solution:** randomly rewire **two edges** at a time.

## People thinking about people:

### How are social networks structured?

- ▶ How do we define and measure connections?
- ▶ Methods/issues of self-report and remote sensing.

### What about the dynamics of social networks?

- ▶ How do social networks/movements begin & evolve?
- ▶ How does collective problem solving work?
- ▶ How does information move through social networks?
- ▶ Which rules give the best 'game of society'?

### Sociotechnical phenomena and algorithms:

- ▶ What can people and computers do together? (google)
- ▶ Use Play + Crunch to solve problems. Which problems?

## General random rewiring algorithm

- ▶ Randomly choose **two edges**. (Or choose problem edge and a random edge)
- ▶ Check to make sure edges are **disjoint**.

- ▶ Rewire one end of each edge.
- ▶ Node degrees **do not change**.
- ▶ Works if  $e_1$  is a self-loop or repeated edge.
- ▶ Same as finding on/off/on/off 4-cycles. and rotating them.

## Social Search

### A small slice of the pie:

- ▶ **Q.** Can people pass messages between distant individuals using only their existing social connections?
- ▶ **A.** Apparently yes...

## Sampling random networks

### Phase 2:

- ▶ Use rewiring algorithm to remove all self and repeat loops.

### Phase 3:

- ▶ **Randomize network** wiring by applying rewiring algorithm liberally.
- ▶ Rule of thumb: # Rewirings  $\approx 10 \times$  # edges<sup>[10]</sup>.

## Milgram's social search experiment (1960s)

<http://www.stanleymilgram.com>

- ▶ Target person = Boston stockbroker.
- ▶ 296 senders from Boston and Omaha.
- ▶ 20% of senders reached target.
- ▶ chain length  $\approx 6.5$ .

### Popular terms:

- ▶ The Small World Phenomenon;
- ▶ "Six Degrees of Separation."

# Social search—the Columbia experiment

- ▶ 60,000+ participants in 166 countries
- ▶ 18 targets in 13 countries including
  - ▶ a professor at an Ivy League university,
  - ▶ an archival inspector in Estonia,
  - ▶ a technology consultant in India,
  - ▶ a policeman in Australia,
  - and
  - ▶ a veterinarian in the Norwegian army.
- ▶ 24,000+ chains

We were lucky and contagious (more later):  
 “Using E-Mail to Count Connections” (田), Sarah Milstein, *New York Times*, Circuits Section (December, 2001)

# Social search—the Columbia experiment

- ▶ Milgram's participation rate was roughly 75%
- ▶ Email version: Approximately 37% participation rate.
- ▶ Probability of a chain of length 10 getting through:  
 $.37^{10} \approx 5 \times 10^{-5}$
- ▶ ⇒ 384 completed chains (1.6% of all chains).

## Social search—the Columbia experiment

- ▶ Motivation/Incentives/Perception matter.
- ▶ If target *seems* reachable  
⇒ participation more likely.
- ▶ Small changes in attrition rates  
⇒ large changes in completion rates
- ▶ e.g., ↘ 15% in attrition rate  
⇒ ↗ 800% in completion rate

## Social search—the Columbia experiment

Nevertheless, some weak discrepancies do exist...

Contrived hypothetical above average connector:

Norwegian, secular male, aged 30-39, earning over \$100K, with graduate level education working in mass media or science, who uses relatively weak ties to people they met in college or at work.

Contrived hypothetical below average connector:

Italian, Islamic or Christian female earning less than \$2K, with elementary school education and retired, who uses strong ties to family members.

## Social search—the Columbia experiment

Successful chains disproportionately used:

- ▶ Weak ties, Granovetter<sup>[7]</sup>
- ▶ Professional ties (34% vs. 13%)
- ▶ Ties originating at work/college
- ▶ Target's work (65% vs. 40%)

...and disproportionately avoided

- ▶ hubs (8% vs. 1%) (+ no evidence of funnels)
- ▶ family/friendship ties (60% vs. 83%)

Geography → Work

## Social search—the Columbia experiment

Mildly bad for continuing chain:

choosing recipients because "they have lots of friends" or because they will "likely continue the chain."

Why:

- ▶ Specificity important
- ▶ Successful links used relevant information. (e.g. connecting to someone who shares same profession as target.)

## Social search—the Columbia experiment

### Basic results:

- ▶  $\langle L \rangle = 4.05$  for all completed chains
- ▶  $L_*$  = Estimated 'true' median chain length (zero attrition)
- ▶ Intra-country chains:  $L_* = 5$
- ▶ Inter-country chains:  $L_* = 7$
- ▶ All chains:  $L_* = 7$
- ▶ Milgram:  $L_* \approx 9$

## Usefulness:

### Harnessing social search:

- ▶ Can distributed social search be used for something big/good?
- ▶ What about something evil? (Good idea to check.)
- ▶ What about socio-inspired algorithms for information search? (More later.)
- ▶ For real social search, we have an incentives problem.
- ▶ Which kind of influence mechanisms/algorithms would help propagate search?
- ▶ Fun, money, prestige, ... ?
- ▶ Must be 'non-gameable.'

## Finding red balloons:

### The winning team and strategy:

- ▶ MIT's [Media Lab](#) (田) won in less than 9 hours.<sup>[11]</sup>
- ▶ Pickard et al. "Time-Critical Social Mobilization,"<sup>[11]</sup> Science Magazine, 2011.
- ▶ People were virally recruited online to help out.
- ▶ Idea: Want people to both (1) find the balloons, and (2) involve more people.
- ▶ Recursive incentive structure with exponentially decaying payout:
  - ▶ \$2000 for correctly reporting the coordinates of a balloon.
  - ▶ \$1000 for recruiting a person who finds a balloon.
  - ▶ \$500 for recruiting a person who recruits the balloon finder, ...
  - ▶ (Not a Ponzi scheme.)
- ▶ True victory: [Colbert interviews Riley Crane](#) (田)

## Red balloons:

### A Grand Challenge:

- ▶ 1969: [The Internet is born](#) (田) (the [ARPANET](#) (田)—four nodes!).
- ▶ Originally funded by DARPA who created a grand [Network Challenge](#) (田) for the 40th anniversary.
- ▶ Saturday December 5, 2009: DARPA puts 10 red weather balloons up during the day.
- ▶ Each 8 foot diameter balloon is anchored to the ground [somewhere in the United States](#).
- ▶ Challenge: Find the latitude and longitude of each balloon.
- ▶ Prize: **\$40,000**.

\*DARPA = [Defense Advanced Research Projects Agency](#) (田).

## Finding balloons:

### Clever scheme:

- ▶ Max payout = \$4000 per balloon.
- ▶ Individuals have clear incentives to both
  1. **involve/source more people** (spread), and
  2. **find balloons** (goal action).
- ▶ Gameable?
- ▶ Limit to how much money a set of bad actors can extract.

### Extra notes:

- ▶ MIT's brand helped greatly.
- ▶ MIT group first heard about the competition a few days before. **Ouch**.
- ▶ A number of other teams **did well** (田).
- ▶ Worthwhile looking at these competing strategies.<sup>[11]</sup>

# The social world appears to be small... why?

Theory: how do we understand the small world property?

- ▶ Connected random networks have short average path lengths:

$$\langle d_{AB} \rangle \sim \log(N)$$

$N$  = population size,

$d_{AB}$  = distance between nodes  $A$  and  $B$ .

- ▶ But: social networks aren't random...

## Previous work—finding short paths

Kleinberg's Network:

1. Start with regular  $d$ -dimensional cubic lattice.
2. Add local links so nodes know all nodes within a distance  $q$ .
3. Add  $m$  short cuts per node.
4. Connect  $i$  to  $j$  with probability

$$p_{ij} \propto x_{ij}^{-\alpha}.$$

- ▶  $\alpha = 0$ : random connections.
- ▶  $\alpha$  large: reinforce local connections.
- ▶  $\alpha = d$ : connections grow logarithmically in space.

## Previous work—finding short paths

Theoretical optimal search:

- ▶ “Greedy” algorithm.
- ▶ Number of connections grow logarithmically (slowly) in space:  $\alpha = d$ .
- ▶ Social golf.

Search time grows slowly with system size (like  $\log^2 N$ ).

But: social networks aren't lattices plus links.

## Previous work—finding short paths

- ▶ If networks have hubs can also search well: Adamic et al. (2001) <sup>[1]</sup>

$$P(k_i) \propto k_i^{-\gamma}$$

where  $k$  = degree of node  $i$  (number of friends).

- ▶ Basic idea: get to hubs first (airline networks).
- ▶ **But: hubs in social networks are limited.**

## The problem

If there are no hubs and no underlying lattice, how can search be efficient?

Which friend of  $a$  is closest to the target  $b$ ?

What does 'closest' mean?

What is 'social distance'?

## Models

One approach: incorporate identity.

Identity is formed from attributes such as:

- ▶ Geographic location
- ▶ Type of employment
- ▶ Religious beliefs
- ▶ Recreational activities.

Groups are formed by people with at least one similar attribute.

Attributes  $\Leftrightarrow$  Contexts  $\Leftrightarrow$  Interactions  $\Leftrightarrow$  Networks.

# BA model

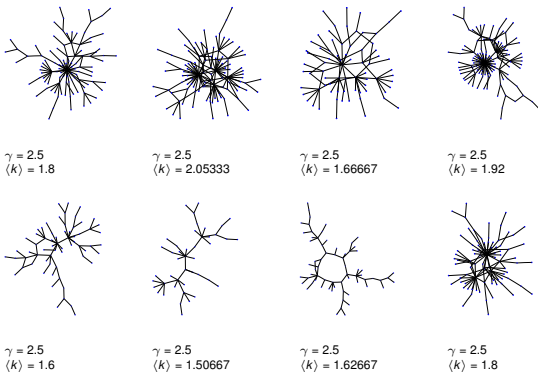

- ▶ Barabási-Albert model = BA model.
- ▶ Key ingredients: **Growth** and **Preferential Attachment (PA)**.
- ▶ **Step 1:** start with  $m_0$  disconnected nodes.
- ▶ **Step 2:**
  1. **Growth**—a new node appears at each time step  $t = 0, 1, 2, \dots$
  2. Each new node makes  $m$  links to nodes already present.
  3. **Preferential attachment**—Probability of connecting to  $i$ th node is  $\propto k_i$ .
- ▶ In essence, we have a **rich-gets-richer** scheme.
- ▶ Yes, we've seen this all before in Simon's model.

# BA model

- ▶ **Definition:**  $A_k$  is the attachment kernel for a node with degree  $k$ .
- ▶ For the original model:

$$A_k = k$$

- ▶ **Definition:**  $P_{attach}(k, t)$  is the attachment probability.
- ▶ For the original model:

$$P_{attach}(\text{node } i, t) = \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = \frac{k_i(t)}{\sum_{k=0}^{k_{max}(t)} k N_k(t)}$$

where  $N(t) = m_0 + t$  is # nodes at time  $t$  and  $N_k(t)$  is # degree  $k$  nodes at time  $t$ .

## Approximate analysis

- ▶ When  $(N + 1)$ th node is added, the expected increase in the degree of node  $i$  is

$$E(k_{i,N+1} - k_{i,N}) \simeq m \frac{k_{i,N}}{\sum_{j=1}^{N(t)} k_j(t)}$$

- ▶ Assumes probability of being connected to is **small**.
- ▶ Dispense with Expectation by assuming (hoping) that over longer time frames, degree growth will be smooth and stable.
- ▶ Approximate  $k_{i,N+1} - k_{i,N}$  with  $\frac{d}{dt}k_{i,t}$ :

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)}$$

where  $t = N(t) - m_0$ .

## Approximate analysis

- ▶  $m = 3$
- ▶  $t_{i,start} = 1, 2, 5, \text{ and } 10$ .

## Approximate analysis

- ▶ Deal with denominator: each added node brings  $m$  new edges.

$$\therefore \sum_{j=1}^{N(t)} k_j(t) = 2tm$$

- ▶ The node degree equation now simplifies:

$$\frac{d}{dt}k_{i,t} = m \frac{k_i(t)}{\sum_{j=1}^{N(t)} k_j(t)} = m \frac{k_i(t)}{2mt} = \frac{1}{2t}k_i(t)$$

- ▶ Rearrange and solve:

$$\frac{dk_i(t)}{k_i(t)} = \frac{dt}{2t} \Rightarrow k_i(t) = c_i t^{1/2}$$

- ▶ Next find  $c_i \dots$

## Degree distribution

- ▶ So what's the degree distribution at time  $t$ ?
- ▶ Use fact that birth time for added nodes is distributed uniformly between time 0 and  $t$ :

$$\Pr(t_{i,start}) dt_{i,start} \simeq \frac{dt_{i,start}}{t}$$

- ▶ Also use

$$k_i(t) = m \left( \frac{t}{t_{i,start}} \right)^{1/2} \Rightarrow t_{i,start} = \frac{m^2 t}{k_i(t)^2}$$

Transform variables—Jacobian:

$$\frac{dt_{i,start}}{dk_i} = -2 \frac{m^2 t}{k_i(t)^3}$$

## Approximate analysis

- ▶ Know  $i$ th node appears at time

$$t_{i,start} = \begin{cases} i - m_0 & \text{for } i > m_0 \\ 0 & \text{for } i \leq m_0 \end{cases}$$

- ▶ So for  $i > m_0$  (exclude initial nodes), we must have

$$k_i(t) = m \left( \frac{t}{t_{i,start}} \right)^{1/2} \text{ for } t \geq t_{i,start}$$

- ▶ All node degrees grow as  $t^{1/2}$  but later nodes have larger  $t_{i,start}$  which **flattens out** growth curve.
- ▶ First-mover advantage: Early nodes do **best**.

## Degree distribution

$$\begin{aligned} \Pr(k_i) dk_i &= \Pr(t_{i,start}) dt_{i,start} \\ &= \Pr(t_{i,start}) dk_i \left| \frac{dt_{i,start}}{dk_i} \right| \\ &= \frac{1}{t} dk_i 2 \frac{m^2 t}{k_i(t)^3} \\ &= 2 \frac{m^2}{k_i(t)^3} dk_i \\ &\propto k_i^{-3} dk_i \end{aligned}$$

## Degree distribution

- ▶ We thus have a very specific prediction of  $\Pr(k) \sim k^{-\gamma}$  with  $\gamma = 3$ .
- ▶ Typical for real networks:  $2 < \gamma < 3$ .
- ▶ Range true more generally for events with size distributions that have power-law tails.
- ▶  $2 < \gamma < 3$ : finite mean and 'infinite' variance (**wild**)
- ▶ In practice,  $\gamma < 3$  means variance is governed by upper cutoff.
- ▶  $\gamma > 3$ : finite mean and variance (**mild**)

## Things to do and questions

- ▶ Vary attachment kernel.
- ▶ Vary mechanisms:
  1. Add edge deletion
  2. Add node deletion
  3. Add edge rewiring
- ▶ Deal with directed versus undirected networks.
- ▶ **Important Q.:** Are there distinct universality classes for these networks?
- ▶ **Q.:** How does changing the model affect  $\gamma$ ?
- ▶ **Q.:** Do we need preferential attachment and growth?
- ▶ **Q.:** Do model details matter? Maybe . . .

## Preferential attachment

- ▶ Let's look at preferential attachment (PA) a little more closely.
- ▶ PA implies arriving nodes have **complete knowledge** of the existing network's degree distribution.
- ▶ For example: If  $P_{attach}(k) \propto k$ , we need to determine the constant of proportionality.
- ▶ We need to know what everyone's degree is...
- ▶ PA is  $\therefore$  an **outrageous** assumption of node capability.
- ▶ But a **very simple mechanism** saves the day. . .

## Preferential attachment through randomness

- ▶ Instead of attaching preferentially, allow new nodes to attach randomly.
- ▶ Now add an **extra step**: new nodes then connect to some of their friends' friends.
- ▶ Can also do this **at random**.
- ▶ Assuming the existing network is random, we know probability of a **random friend** having degree  $k$  is

$$Q_k \propto kP_k$$

- ▶ So **rich-gets-richer** scheme can now be seen to work in a natural way.
- ▶ Later: we'll see that the nature of  $Q_k$  means your friends have more friends that you. **#disappointing**

# Generalized model

- ▶ Here's the set up:

$$\frac{dN_k}{dt} = \frac{1}{A} [A_{k-1}N_{k-1} - A_kN_k] + \delta_{k1}$$

where  $N_k$  is the number of nodes of degree  $k$ .

1. One node with one link is added per unit time.
2. The first term corresponds to degree  $k - 1$  nodes becoming degree  $k$  nodes.
3. The second term corresponds to degree  $k$  nodes becoming degree  $k - 1$  nodes.
4.  $A$  is the correct normalization (coming up).
5. Seed with some initial network (e.g., a connected pair)
6. Detail:  $A_0 = 0$

# Core Models of Complex Networks

- Generalized random networks
- Small-world networks
- Scale-free networks
- Robustness
- References

# Robustness

- ▶ Scale-free networks are thus **robust to random failures** yet **fragile to targeted ones**.
- ▶ All very reasonable: **Hubs** are a big deal.
- ▶ **But**: next issue is whether hubs are vulnerable or not.
- ▶ Representing all webpages as the same size node is obviously a stretch (e.g., google vs. a random person's webpage)
- ▶ Most connected nodes are either:
  1. Physically larger nodes that may be harder to 'target'
  2. or subnetworks of smaller, normal-sized nodes.
- ▶ Need to explore cost of various targeting schemes.

# Core Models of Complex Networks

- Generalized random networks
- Small-world networks
- Scale-free networks
- Robustness
- References

# Generalized model

- ▶ In general, probability of attaching to a **specific node** of degree  $k$  at time  $t$  is

$$\Pr(\text{attach to node } i) = \frac{A_k}{A(t)}$$

where  $A(t) = \sum_{k=1}^{\infty} A_k N_k(t)$ .

- ▶ E.g., for BA model,  $A_k = k$  and  $A = \sum_{k=1}^{\infty} k N_k(t)$ .
- ▶ For  $A_k = k$ , we have

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) = 2t$$

since one edge is being added per unit time.

- ▶ Detail: we are ignoring initial seed network's edges.

# Core Models of Complex Networks

- Generalized random networks
- Small-world networks
- Scale-free networks
- Robustness
- References

## Generalized model

- ▶ So now

$$\frac{dN_k}{dt} = \frac{1}{A} [A_{k-1}N_{k-1} - A_k N_k] + \delta_{k1}$$

becomes

$$\frac{dN_k}{dt} = \frac{1}{2t} [(k-1)N_{k-1} - kN_k] + \delta_{k1}$$

- ▶ As for BA method, look for steady-state growing solution:  $N_k = n_k t$ .
- ▶ We replace  $dN_k/dt$  with  $dn_k t/dt = n_k$ .
- ▶ We arrive at a difference equation:

$$n_k = \frac{1}{2t} [(k-1)n_{k-1}t - kn_k t] + \delta_{k1}$$

## Universality?

- ▶ For  $A_k = k$  we had

$$n_k = \frac{1}{2} [(k-1)n_{k-1} - kn_k] + \delta_{k1}$$

- ▶ This now becomes

$$n_k = \frac{1}{\mu} [A_{k-1}n_{k-1} - A_k n_k] + \delta_{k1}$$

$$\Rightarrow (A_k + \mu)n_k = A_{k-1}n_{k-1} + \mu\delta_{k1}$$

- ▶ Again two cases:

$$k = 1 : n_1 = \frac{\mu}{\mu + A_1}; \quad k > 1 : n_k = n_{k-1} \frac{A_{k-1}}{\mu + A_k}$$

## Universality?

- ▶ Insert question from assignment 7 (田)  
As expected, we have the same result as for the BA model:

$$N_k(t) = n_k(t)t \propto k^{-3} \text{ for large } k.$$

- ▶ Now: what happens if we start playing around with the attachment kernel  $A_k$ ?
- ▶ Again, we're asking if the result  $\gamma = 3$  universal (田)?
- ▶ KR's natural modification:  $A_k = k^\nu$  with  $\nu \neq 1$ .
- ▶ But we'll first explore a more subtle modification of  $A_k$  made by Krapivsky/Redner<sup>[9]</sup>
- ▶ Keep  $A_k$  linear in  $k$  but tweak details.
- ▶ **Idea:** Relax from  $A_k = k$  to  $A_k \sim k$  as  $k \rightarrow \infty$ .

## Universality?

- ▶ Time for pure excitement: Find **asymptotic behavior** of  $n_k$  given  $A_k \rightarrow k$  as  $k \rightarrow \infty$ .
- ▶ Insert question from assignment 7 (田)  
For large  $k$ , we find:

$$n_k = \frac{\mu}{A_k} \prod_{j=1}^k \frac{1}{1 + \frac{\mu}{A_j}} \propto k^{-\mu-1}$$

- ▶ Since  $\mu$  depends on  $A_k$ , **details matter...**

## Universality?

- ▶ Recall we used the normalization:

$$A(t) = \sum_{k'=1}^{\infty} k' N_{k'}(t) \simeq 2t \text{ for large } t.$$

- ▶ We now have

$$A(t) = \sum_{k'=1}^{\infty} A_{k'} N_{k'}(t)$$

where we only know the asymptotic behavior of  $A_k$ .

- ▶ We assume that  $A = \mu t$
- ▶ We'll find  $\mu$  later and make sure that our assumption is consistent.
- ▶ As before, also assume  $N_k(t) = n_k t$ .

## Universality?

- ▶ Now we need to find  $\mu$ .
- ▶ Our assumption again:  $A = \mu t = \sum_{k=1}^{\infty} N_k(t) A_k$
- ▶ Since  $N_k = n_k t$ , we have the simplification  $\mu = \sum_{k=1}^{\infty} n_k A_k$
- ▶ Now substitute in our expression for  $n_k$ :

$$1\mu = \sum_{k=1}^{\infty} \frac{\mu}{A_k} \prod_{j=1}^k \frac{1}{1 + \frac{\mu}{A_j}} A_k$$

- ▶ Closed form expression for  $\mu$ .
- ▶ We can solve for  $\mu$  in some cases.
- ▶ Our assumption that  $A = \mu t$  looks to be not too horrible.

## Universality?

- ▶ Consider tunable  $A_1 = \alpha$  and  $A_k = k$  for  $k \geq 2$ .
- ▶ Again, we can find  $\gamma = \mu + 1$  by finding  $\mu$ .
- ▶ Insert question from assignment 7 (田)  
Closed form expression for  $\mu$ :

$$\frac{\mu}{\alpha} = \sum_{k=2}^{\infty} \frac{\Gamma(k+1)\Gamma(2+\mu)}{\Gamma(k+\mu+1)}$$

#mathisfun

$$\mu(\mu-1) = 2\alpha \Rightarrow \mu = \frac{1 + \sqrt{1+8\alpha}}{2}$$

- ▶ Since  $\gamma = \mu + 1$ , we have

$$0 \leq \alpha < \infty \Rightarrow 2 \leq \gamma < \infty$$

- ▶ Crazyiness...

## Superlinear attachment kernels

- ▶ Rich-get-much-richer:

$$A_k \sim k^\nu \text{ with } \nu > 1.$$

- ▶ Now a **winner-take-all** mechanism.
- ▶ One single node ends up being connected to almost all other nodes.
- ▶ For  $\nu > 2$ , all but a finite # of nodes connect to one node.

## Sublinear attachment kernels

- ▶ Rich-get-somewhat-richer:

$$A_k \sim k^\nu \text{ with } 0 < \nu < 1.$$

- ▶ General finding by Krapivsky and Redner: [9]

$$n_k \sim k^{-\nu} e^{-c_1 k^{1-\nu} + \text{correction terms}}$$

- ▶ Stretched exponentials (truncated power laws).
- ▶ aka Weibull distributions.
- ▶ **Universality**: now details of kernel **do not** matter.
- ▶ Distribution of degree is universal providing  $\nu < 1$ .

## Nutshell:

### Overview Key Points for Models of Networks:

- ▶ Obvious connections with the vast extant field of graph theory.
- ▶ But focus on dynamics is more of a physics/stat-mech/comp-sci flavor.
- ▶ Two main areas of focus:
  1. **Description**: Characterizing very large networks
  2. **Explanation**: Micro story  $\Rightarrow$  Macro features
- ▶ Some essential structural aspects are understood: degree distribution, clustering, assortativity, group structure, overall structure,...
- ▶ Still much work to be done, especially with respect to dynamics... **#excitement**

## Sublinear attachment kernels

### Details:

- ▶ For  $1/2 < \nu < 1$ :

$$n_k \sim k^{-\nu} e^{-\mu \left( \frac{k^{1-\nu} - 2^{1-\nu}}{1-\nu} \right)}$$

- ▶ For  $1/3 < \nu < 1/2$ :

$$n_k \sim k^{-\nu} e^{-\mu \frac{k^{1-\nu}}{1-\nu} + \frac{\mu^2}{2} \frac{k^{1-2\nu}}{1-2\nu}}$$

- ▶ And for  $1/(r+1) < \nu < 1/r$ , we have  $r$  pieces in exponential.
