Scaling

Aeasuring allomet

Scaling

metric argu

General observation:

Systems (complex or not) that cross many spatial and temporal scales often exhibit some form of scaling.

Outline—All about scaling:

- Definitions.
- Examples.
- How to measure your power-law relationship.
- Scaling in metabolism and river networks.
- The Unsolved Allometry Theoricides.

Definitions

A power law relates two variables x and y as follows:

 $V = CX^{\alpha}$

- α is the scaling exponent (or just exponent)
- (α can be any number in principle but we will find various restrictions.)
- c is the prefactor (which can be important!)

Definitions

- ▶ The prefactor c must balance dimensions.
- Imagine the height ℓ and volume v of a family of shapes are related as:

$$\ell = cv^{1/4}$$

▶ Using [·] to indicate dimension, then

$$[c] = [l] / [V^{1/4}] = L/L^{3/4} = L^{1/4}.$$

Looking at data

Power-law relationships are linear in log-log space:

$$y = cx^{\alpha}$$

$$\Rightarrow \log_b y = \alpha \log_b x + \log_b c$$

with slope equal to α , the scaling exponent.

- Much searching for straight lines on log-log or double-logarithmic plots.
- ► Good practice: Always, always, always use base 10.
- Talk only about orders of magnitude (powers of 10).

References

UNIVERSITY

Why is $\alpha \simeq 1.23$?

A rough understanding:

- We are here: $W \propto G^{4/3}/T$
- Observe weak scaling $T \propto G^{0.10\pm0.02}$.
- (Implies $S \propto G^{0.9} \rightarrow$ convolutions fill space.)
- \blacktriangleright \Rightarrow $W \propto G^{4/3}/T \propto G^{1.23\pm0.02}$

$\log_{10} W = (1.174 \pm 0.007) \log_{10} V - (1.40 \pm 0.03)$

- With V = G + W, some power laws must be
- Measuring exponents is a hairy business...

Good scaling:

General rules of thumb:

- High quality: scaling persists over three or more orders of magnitude for each variable.
- Medium quality: scaling persists over three or more orders of magnitude for only one variable and at least one for the other.
- Very dubious: scaling 'persists' over less than an order of magnitude for both variables.

A beautiful, heart-warming example:

10

10

10

10

White

• G = volume of gray matter: 'computing elements'

- W = volume of white matter: 'wiring'
- ▶ *W* ~ *cG*^{1.23}

Why is $\alpha \simeq 1.23$?

Scaling

Quantities (following Zhang and Sejnowski):

- G = Volume of gray matter (cortex/processors)
- W = Volume of white matter (wiring)
- T =Cortical thickness (wiring)
- ► S = Cortical surface area
- L = Average length of white matter fibers
- p = density of axons on white matter/cortex interface

A rough understanding:

- $G \sim ST$ (convolutions are okay)
- \blacktriangleright $W \sim \frac{1}{2}pSL$
- $G \sim L^3 \leftarrow$ this is a little sketchy...
- Eliminate S and L to find $W \propto G^{4/3}/T$

Scaling-at-large

References

•) < (~ 9 of 145

from Zhang & Sejnowski, PNAS (2000)^[54]

 $\log_{10} W = (1.23 \pm 0.01) \log_{10} G - (1.47 \pm 0.04)$

r = 0.998

10³ 10⁴ Gray Matter Volume G (mm³)

Trickiness:

10 $\log_{10} G = (0.955 \pm 0.002) \log_{10} V + (0.061 \pm 0.009)$ 10 10 10

r = 0.9988 10

- 10^3 10^4 10^5 10^6 Total Volume V = G + W (mm³)
- approximations.

₹ 210 10 10

Scaling

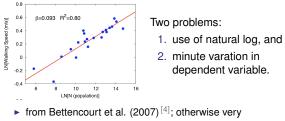

Scaling

Scaling-at-large

Scaling-at-large

Unconvincing scaling:

Average walking speed as a function of city population:

interesting-see later.

Definitions

Power laws are the signature of scale invariance:

Scale invariant 'objects' look the 'same' when they are appropriately rescaled.

- Objects = geometric shapes, time series, functions, relationships, distributions,...
- Same' might be 'statistically the same'
- To rescale means to change the units of measurement for the relevant variables

Our friend $y = cx^{\alpha}$:

- If we rescale x as x = rx' and y as $y = r^{\alpha}y'$,
- then
- $r^{\alpha} y' = c(rx')^{\alpha}$

Scaling

Isometry:

Definitions:

Scale invariance

More on $v = ce^{-\lambda x}$:

For $x \gg x_0$, y is small,

while for $x \ll x_0$, y is large.

Compare with $y = ce^{-\lambda x}$:

• If we rescale x as x = rx', then

Original form cannot be recovered.

Scale matters for the exponential.

Say $x_0 = 1/\lambda$ is the characteristic scale.

 $y = ce^{-\lambda rx'}$

with each other.

Allometry:

Dimensions scale nonlinearly.

Dimensions scale linearly

Allometry: (⊞)

- Refers to differential growth rates of the parts of a living organism's body part or process.
- First proposed by Huxley and Teissier, Nature, 1936 "Terminology of relative growth" [23, 45]

Definitions

Isometry versus Allometry:

- Iso-metry = 'same measure'
- Allo-metry = 'other measure'

Confusingly, we use allometric scaling to refer to both:

- 1. Nonlinear scaling of a dependent variable on an independent one (e.g., $y \propto x^{1/3}$)
- 2. The relative scaling of correlated measures (e.g., white and gray matter).

Engines:

The allometry of nails:

Observed: Diameter \propto Length^{2/3} or $d \propto \ell^{2/3}$.

Since $\ell d^2 \propto$ Volume *v*:

- Diameter \propto Mass^{2/7} or $d \propto v^{2/7}$.
- Length \propto Mass^{3/7} or $\ell \propto v^{3/7}$.
- Nails lengthen faster than they broaden (c.f. trees).
- p. 58–59, McMahon and Bonner^[31]

A buckling instability?:

- ► Physics/Engineering result (⊞): Columns buckle under a load which depends on d^4/ℓ^2 .
- To drive nails in, posit resistive force \propto nail circumference = πd .
- Match forces independent of nail size: $d^4/\ell^2 \propto d$.
- Leads to $d \propto \ell^{2/3}$.
- Argument made by Galileo^[15] in 1638 in "Discourses on Two New Sciences." (⊞) Also, see here. (⊞)
- ▶ Euler, 1757. (⊞)

Intriguing findings:

- Global supply costs scale sublinearly with N ($\beta < 1$). Returns to scale for infrastructure.
- Total individual costs scale linearly with N ($\beta = 1$)
 - Individuals consume similar amounts independent of city size.
- Social quantities scale superlinearly with N ($\beta > 1$)
 - Creativity (# patents), wealth, disease, crime, ...

Density doesn't seem to matter...

 Surprising given that across the world, we observe two orders of magnitude variation in area covered by agglomerations (\boxplus) of fixed populations.

Relationship to ordinary least squares regression is simple:

$$slope_{SMA} = r^{-1} \times slope_{OLS y on}$$

= $r \times slope_{OLS y on y}$

where r = standard correlation coefficient:

$$=\frac{\sum_{i=1}^{n}(x_{i}-\bar{x})(y_{i}-\bar{y})}{\sqrt{\sum_{i=1}^{n}(x_{i}-\bar{x})^{2}}\sqrt{\sum_{i=1}^{n}(y_{i}-\bar{y})^{2}}}$$

More on regression:

If (a) we don't know what the errors of either variable are,

or (b) no variable can be considered independent,

then we need to use Standardized Major Axis Linear Regression. [42, 39]

For Standardized Major Axis Linear Regression:

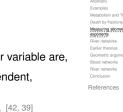

standard deviation of y data

standard deviation of x data

(aka Reduced Major Axis = RMA.)

Hypothesis testing

Test to see if α' is consistent with our data $\{(M_i, B_i)\}$:

$$H_0: \alpha = \alpha' \text{ and } H_1: \alpha \neq \alpha'$$

- Assume each B_i (now a random variable) is normally distributed about $\alpha' \log_{10} M_i + \log_{10} c$.
- Follows that the measured α for one realization obeys a *t* distribution with N - 2 degrees of freedom.
- Calculate a *p*-value: probability that the measured α is as least as different to our hypothesized α' as we observe.
- See, for example, DeGroot and Scherish, "Probability and Statistics." [10]

Analysis of residuals

- 1. Presume an exponent of your choice: 2/3 or 3/4.
- 2. Fit the prefactor $(\log_{10} c)$ and then examine the residuals:

$$r_i = \log_{10} B_i - (\alpha' \log_{10} M_i - \log_{10} c).$$

- 3. H₀: residuals are uncorrelated H₁: residuals are correlated.
- 4. Measure the correlations in the residuals and compute a p-value.

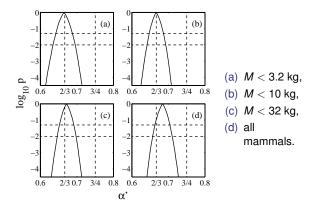

Measuring allometric exponents

Analysis of residuals-mammals

VERMONT

Scaling

Analysis of residuals

We use the spiffing Spearman Rank-Order Correlation Cofficient (⊞)

Basic idea:

- Given $\{(x_i, y_i)\}$, rank the $\{x_i\}$ and $\{y_i\}$ separately from smallest to largest. Call these ranks R_i and S_i .
- ▶ Now calculate correlation coefficient for ranks, r_s:

$$r_{s} = rac{\sum_{i=1}^{n} (R_{i} - \bar{R})(S_{i} - \bar{S})}{\sqrt{\sum_{i=1}^{n} (R_{i} - \bar{R})^{2}} \sqrt{\sum_{i=1}^{n} (S_{i} - \bar{S})^{2}}}$$

Perfect correlation: x_i's and y_i's both increase monotonically.

Analysis of residuals

We assume all rank orderings are equally likely:

- r_s is distributed according to a Student's *t*-distribution (\boxplus) with N - 2 degrees of freedom.
- Excellent feature: Non-parametric—real distribution of x's and y's doesn't matter.
- Bonus: works for non-linear monotonic relationships as well.
- ► See Numerical Recipes in C/Fortran (⊞) which contains many good things. [37]

Other approaches to measuring exponents:

- Clauset, Shalizi, Newman: "Power-law distributions in empirical data" [9] SIAM Review, 2009.
- See Clauset's page on measuring power law exponents (\boxplus) (code, other goodies).

Impedance measures:

Poiseuille flow (outer branches):

$$Z = \frac{8\mu}{\pi} \sum_{k=0}^{N} \frac{\ell_k}{r_k^4 N_k}$$

Pulsatile flow (main branches):

- Wheel out Lagrange multipliers
- Poiseuille gives $P \propto M^1$ with a logarithmic correction.
- Pulsatile calculation explodes into flames.

 $\triangleright P \propto M^{3/4}$

Not so fast ...

Actually, model shows:

- $P \propto M^{3/4}$ does not follow for pulsatile flow
- networks are not necessarily fractal.

Do find:

▶ Murray's cube law (1927) for outer branches: [34]

$$r_0^3 = r_1^3 + r_2^3$$

- Impedance is distributed evenly.
- Can still assume networks are fractal.

Connecting network structure to α

1. Ratios of network parameters:

$$R_n = \frac{n_{k+1}}{n_k}, \ R_\ell = \frac{\ell_{k+1}}{\ell_k}, \ R_r = \frac{r_{k+1}}{r_k}$$

2. Number of capillaries $\propto P \propto M^{\alpha}$.

$$\Rightarrow \quad \alpha = -\frac{\ln R_n}{\ln R_r^2 R_\ell}$$

(also problematic due to prefactor issues)

Obliviously soldiering on, we could assert:

- area-preservingness: $R_r = R_n^{-1/2}$
- ▶ space-fillingness: $R_{\ell} = R_n^{-1/3}$

Data from real networks:

Gas

Minimal network volume:

Minimal network volume:

Approximate network volume by integral over region:

$$\begin{split} \min V_{\text{net}} & \propto \int_{\Omega_{d,D}(V)} \rho ||\vec{x}|| \, \mathrm{d}\vec{x} \\ & \rightarrow \rho V^{1+\gamma_{\text{max}}} \int_{\Omega_{d,D}(c)} (c_1^2 u_1^2 + \ldots + c_k^2 u_k^2)^{1/2} \mathrm{d}\vec{u} \end{split}$$

Insert question from assignment 10 (⊞)

$$\propto \rho V^{1+\gamma_{ma}}$$

Geometric argument

General result:

min $V_{\rm net} \propto \rho V^{1+\gamma_{\rm max}}$

• If scaling is isometric, we have $\gamma_{max} = 1/d$:

min
$$V_{\rm net/iso} \propto \rho V^{1+1/d} = \rho V^{(d+1)/d}$$

• If scaling is allometric, we have $\gamma_{max} = \gamma_{allo} > 1/d$: and

min
$$V_{\rm net/allo} \propto \rho V^{1+\gamma_{\rm allo}}$$

Isometrically growing volumes require less network volume than allometrically growing volumes:

 $\frac{\text{min }V_{\text{net/iso}}}{\text{min }V_{\text{net/allo}}} \rightarrow 0 \text{ as }V \rightarrow \infty$

Blood networks

Blood networks

- ► Material costly ⇒ expect lower optimal bound of $V_{\rm net} \propto \rho V^{(d+1)/d}$ to be followed closely.
- For cardiovascular networks, d = D = 3.
- ▶ Blood volume scales linearly with body volume ^[47], $V_{\rm net} \propto V$.
- ▶ Sink density must ∴ decrease as volume increases:

$\rho \propto V^{-1/d}$.

size.

• Then *P*, the rate of overall energy use in Ω , can at

For d = 3 dimensional organisms, we have

Scaling-at-large River networks References

River networks

- View river networks as collection networks.
- Many sources and one sink.
- Assume ρ is constant over time:

$$V_{\rm net} \propto \rho V^{(d+1)/d} = {\rm constant} \times V^{3/2}$$

- Network volume grows faster than basin 'volume' (really area).
- It's all okay: Landscapes are d=2 surfaces living in D=3dimensions.
- Streams can grow not just in width but in depth...

Hack's law

- Volume of water in river network can be calculated by adding up basin areas
- Flows sum in such a way that

$$V_{
m net} = \sum_{
m all \ pixels} a_{
m pixel \ i}$$

Hack's law again:

$$\ell \sim a^h$$

Can argue

$$V_{\rm net} \propto V_{\rm basin}^{1+n} = a_{\rm basin}^{1+n}$$

where *h* is Hack's exponent.

▶ ∴ minimal volume calculations gives

ν

$$h = 1/2$$

Artisanal, handcrafted stupidity:

"Critical truths about power laws" [48] Stumpf and Porter, Science, 2012

 Call generalization of Central Limit Theorem, stable distributions. Also: PLIPLO action.

Summary: Wow.

Conclusion

- Supply network story consistent with dimensional analysis.
- Isometrically growing regions can be more efficiently supplied than allometrically growing ones.
- Ambient and region dimensions matter (D = d versus D > d).
- Deviations from optimal scaling suggest inefficiency (e.g., gravity for organisms, geological boundaries).
- Actual details of branching networks not that important.
- Exact nature of self-similarity varies.
- 2/3-scaling lives on, largely in hiding.
- 3/4-scaling? Jury ruled a mistrial.
- The truth will out.
